

ELECTRIC CURRENT

EXERCISES

Section 24.1 Electric Current

- 11. INTERPRET** This problem involves converting current in amperes to the number of electrons moving past a given point in a wire per unit time.

DEVELOP Current in amperes is the amount of charge in coulombs passing a given point in the wire, per second. Mathematically, this is given by Equation 24.1a:

$$I = \frac{\Delta q}{\Delta t}$$

To find the number of electrons, divide the charge in coulombs by the charge of a single electron in coulombs ($|e| = 1.60 \times 10^{-19} \text{ C}$).

EVALUATE Solving the expression above for the charge and dividing it by the charge of an electron gives the number n of electrons as

$$n = \frac{\Delta q}{|e|} = \frac{I \Delta t}{|e|} = \frac{(1.4 \text{ A})(1.0 \text{ s})}{1.6 \times 10^{-19} \text{ C}} = 8.75 \times 10^{18}$$

ASSESS Because electrons carry a negative charge, they actually move in the direction opposite to that of the given current.

- 12. INTERPRET** We are to find the charge (in Coulombs) that passes through a circuit given the battery capacity in ampere-hours.

DEVELOP Use Equation 24.1a. A battery capacity of $80 \text{ A} \cdot \text{h}$ means that the battery can supply $I = 80 \text{ A}$ for 1 h . The definition of an ampere is 1 C/s . Inspecting the units shows that we can get the charge by multiplying this current I by the given time Δt over which the battery can supply this current (i.e., $1 \text{ h} = 3600 \text{ s}$).

EVALUATE A battery rated at $80 \text{ A} \cdot \text{h}$ can supply a net charge of

$$\Delta Q = I \Delta t = (80 \text{ C/s})(3600 \text{ s}) = 2.9 \times 10^5 \text{ C}$$

ASSESS By definition, $1 \text{ A} = 1 \text{ C/s}$, or $1 \text{ C} = 1 \text{ A} \cdot \text{s}$, which agree with the units of the right-hand side of our calculation above.

- 13. INTERPRET** This problem involves finding the charge that moves through a membrane over a given time interval, given the current.

DEVELOP From the definition of an ampere, we know that the charge moving through the membrane each second is 30 nC (see Equation 24.1a; $q = I \Delta t$). Since singly charged ions carry one elementary charge (about $q_{\text{ion}} = 160 \text{ zC}$), we can find the total charge that passes through the membrane in one second.

EVALUATE Letting the units guide us, we find the number n of ions that pass the membrane in one second is

$$n = \frac{I \Delta t}{q_{\text{ion}}} = \frac{(29 \text{ nC/s})(1 \text{ s})}{160 \text{ zC/ion}} = 1.81 \times 10^{11} \text{ ion}$$

ASSESS This may also be expressed in terms of the number n_{mol} of moles:

$$n_{\text{mol}} = \frac{1.81 \times 10^{11} \text{ ion}}{6.022 \times 10^{23} \text{ ion/mol}} = 0.30 \text{ pmol}$$

Chemical drug-testing instrumentation can detect such low amounts of substances.

- 14. INTERPRET** In this problem, we are asked to find the current density, given the electric current and the cross section through which it travels.

DEVELOP The current density J is defined as the current per unit area, or $J = I / A$.

EVALUATE The cross section of a wire is uniform, so the density is

$$J = \frac{I}{A} = \frac{13 \text{ A}}{1.5 \times 10^{-6} \text{ m}^2} = 8.7 \times 10^6 \text{ A/m}^2$$

ASSESS This is the average current density. If the cross section were nonuniform, some areas would experience more current density while other areas would experience less.

Section 24.2 Conduction Mechanisms

- 15. INTERPRET** The problem involves the microscopic version of Ohm's law.

DEVELOP Aluminum obeys Ohm's law, so from Equation 24.4b: $J = E / \rho$, where the resistivity of aluminum is given in Table 24.1: $\rho = 2.65 \times 10^{-8} \Omega \cdot \text{m}$.

EVALUATE The current density in the wire is:

$$J = \frac{E}{\rho} = \frac{85 \text{ mV/m}}{2.65 \times 10^{-8} \Omega \cdot \text{m}} = 3.2 \times 10^6 \text{ A/m}^2$$

ASSESS The units work out, since $1 \Omega = 1 \text{ V/A}$.

- 16. INTERPRET** In this problem we are asked to calculate the electric field in a current-carrying conductor.

DEVELOP To find the electric field, use Ohm's law (which applies to silver), $J = E / \rho$, and the definition of current density, which is assumed to be uniform over the wire cross section.

EVALUATE Using Table 24.1 to find the resistivity of silver, the electric field is

$$E = \rho J = \frac{\rho I}{\pi d^2 / 4} = \frac{4(1.59 \times 10^{-8} \Omega \cdot \text{m})(7.5 \text{ A})}{\pi(9.5 \times 10^{-4} \text{ m})^2} = 0.17 \text{ V/m}$$

ASSESS The value is a lot smaller than the electric field we discussed in electrostatic situations. Since silver is such a good conductor, a small field can drive a substantial current.

- 17. INTERPRET** We are asked to find the diameter of a current-carrying cylinder, given the current and the electric field. The resistivity of the cylinder is also known via Table 24.1.

DEVELOP Assuming a uniform current density obeying Ohm's law, apply Equation 24.4b, $J = E / \rho$ to find the current density J . Knowing J , we can find the cylinder diameter using $J = I / A$ (see Example 24.2), where $A = \pi(d/2)^2$.

EVALUATE Combining the expressions above to solve for the diameter d gives

$$J = E / \rho = \frac{I}{\pi(d/2)^2}$$

$$d = \sqrt{\frac{4\rho I}{\pi E}} = 2\sqrt{\frac{(0.22 \Omega \cdot \text{m})(350 \text{ mA})}{\pi(21 \text{ V/m})}} = 6.8 \text{ cm}$$

ASSESS This seems like a reasonable inner diameter for the tube.

- 18. INTERPRET** This problem is about applying Ohm's law to find the resistivity of a rod.
DEVELOP If the rod has a uniform current density and obeys Ohm's law (Equations 24.4a and 24.4b), then its resistivity is

$$\rho = \frac{E}{J} = \frac{E}{I/A} = \frac{E(\pi d^2/4)}{I}$$

EVALUATE Inserting the values given in the problem statement, the resistivity of the rod is

$$\rho = \frac{E(\pi d^2/4)}{I} = \frac{\pi(1.4 \text{ V/m})(10^{-2} \text{ m})^2}{4(50 \text{ A})} = 2.2 \times 10^{-6} \Omega \cdot \text{m}$$

ASSESS With reference to Table 24.1, we see that the value is within the range of resistivity of metallic conductors.

- 19. INTERPRET** Given the resistivity of two materials, we are to find their conductivity.
DEVELOP Equations 24.4a and 24.4b show that the conductivity and the resistivity are reciprocals of one another.
EVALUATE (a) For copper, $\rho^{-1} = \sigma = (1.68 \times 10^{-8} \Omega \cdot \text{m})^{-1} = 5.95 \times 10^7 (\Omega \cdot \text{m})^{-1}$.
 (b) For seawater, $\sigma = (0.22 \Omega \cdot \text{m})^{-1} = 4.55 (\Omega \cdot \text{m})^{-1}$.
ASSESS The salinity of open-ocean water varies between 33 and 37 parts per thousand, but can vary from 1 to 80 parts per thousand in shallow coastal waters. This variation has a proportional effect on the conductivity.

Section 24.3 Resistance and Ohm's Law

- 20. INTERPRET** This problem involves using the macroscopic version of Ohm's law to calculate the resistance of a heating coil.
DEVELOP The macroscopic form of Ohm's law is probably applicable to the heating coil, which is typically a coil of wire. Equation 24.5 gives $R = V/I$.
EVALUATE Inserting the values given in the problem statement, we find the resistance to be

$$R = \frac{V}{I} = \frac{230 \text{ V}}{4.6 \text{ A}} = 50 \Omega$$

ASSESS This is a fairly large resistance. The resistance of the coil used for heating is usually quite high.

- 21. INTERPRET** This problem involves using the macroscopic form of Ohm's law to find the voltage needed to produce a desired current.
DEVELOP For an Ohmic resistor, the macroscopic version of Ohm's law (Equation 24.5) is $V = IR$.
EVALUATE Inserting the given quantities gives $V = IR = (200 \text{ mA})(2.3 \text{ k}\Omega) = 460 \text{ V}$.
ASSESS This is twice the peak voltage provided by standard power outlets in Europe, so it would not be possible to generate this current without employing some method to increase the voltage from the power outlet.
- 22. INTERPRET** In this problem, we want to apply the macroscopic version of Ohm's law to calculate the current across a resistor.
DEVELOP The macroscopic version of Ohm's law, $V = IR$, given in Equation 24.5 provides the connection between current, resistance, and voltage. This equation allows us to compute the current I .
EVALUATE Inserting the values given in the problem statement, we find the current to be

$$I = \frac{V}{R} = \frac{220 \text{ V}}{85 \text{ k}\Omega} = 2.6 \text{ mA}$$

ASSESS From Ohm's law, we see that current is inversely proportional to resistance when V is kept fixed. In our case, a large resistance yields a small current.

- 23. INTERPRET** We are to find the resistance of an iron rail with the given dimensions. This involves using both macroscopic (resistance) and microscopic (resistivity) concepts.
DEVELOP The microscopic resistivity ρ is connected to the macroscopic resistance R by Equation 24.6, $R = \rho L/A$.
EVALUATE Inserting the given quantities gives $R = \rho L/A = (9.71 \times 10^{-8} \Omega \cdot \text{m})(5.0 \text{ km})/(10 \times 15 \text{ cm}^2) = 32 \text{ m}\Omega$.
ASSESS This resistance is quite low, which explains in part why this material is used for this purpose.

- 24. INTERPRET** This problem is about applying the macroscopic version of Ohm's law to calculate the current across a resistor.

DEVELOP The macroscopic version of Ohm's law ($V = IR$) given in Equation 24.5 provides the connection between current, resistance, and voltage. This equation allows us to compute the current I .

EVALUATE Inserting the values given in the problem statement, we find the current is

$$I = \frac{V}{R} = \frac{45 \text{ V}}{1.8 \text{ k}\Omega} = 25 \text{ mA}$$

ASSESS From Ohm's law, we see that current is inversely proportional to resistance when V is kept fixed. These values of current and resistance are typical of what are encountered in common electrical appliances.

- 25. INTERPRET** We are to find the resistance of a wire whose length is doubled while its density remains constant.

DEVELOP If the density (and mass) of the wire remains constant, then its volume is constant, so $V = LA = \text{constant}$. Using the fact that the length is doubled ($2L_1 = L_2$), we can find the new resistance by using Equation 24.6, $R = \rho L/A$.

EVALUATE Taking the ratio of the Equation 24.6 applied to the wire before and after stretching gives

$$\frac{R_1}{R_2} = \frac{\rho L_1/A_1}{\rho L_2/A_2} = \frac{L_1^2/(L_1 A_1)}{L_2^2/(L_2 A_2)} = \frac{L_1^2/(V)}{L_2^2/(V)} = \left(\frac{L_1}{L_2}\right)^2$$

$$R_2 = R_1 \left(\frac{L_2}{L_1}\right)^2 = 4R_1$$

ASSESS The resistance is quadratic in L , so doubling L increases the resistance by a factor of 4.

Section 24.4 Electric Power

- 26. INTERPRET** This problem involves the electric power of a motor. We are given the current drawn and the voltage across the terminals and are to find the power consumed by the motor.

DEVELOP Equation 24.7, $P = IV$, provides the relation between electric current, voltage, and electric power. Apply this equation to compute the power P .

EVALUATE Inserting the values given in the problem, we find the power consumption is

$$P = IV = (120 \text{ A})(11 \text{ V}) = 1.32 \text{ kW}$$

ASSESS A large electric power is needed to start a car. This is why a very high current is required in the starter motor to crank the engine.

- 27. INTERPRET** We are given the power required to operate a device and the current it draws. From this information, we are to find its voltage and resistance.

DEVELOP Apply Equation 24.7, $V = P/I$, to find the voltage and Equation 24.5, $R = V/I$ to find the resistance.

EVALUATE (a) From Equation 24.7, $V = P/I = (4.5 \text{ W})/(750 \text{ mA}) = 6.0 \text{ V}$.

(b) From Equation 24.5, $R = V/I = (6.0 \text{ V})/(0.75 \text{ A}) = 8.0 \Omega$.

ASSESS This is a small voltage and a small resistance, with the ratio giving rise to a significant current.

- 28. INTERPRET** This problem requires us to find the current drawn from a battery, given its voltage and power rating.

DEVELOP Equation 24.7, $P = IV$, provides the relation between electric current, voltage, and electric power.

EVALUATE Rearranging Equation 24.7, we find

$$I = \frac{P}{V} = \frac{210 \mu\text{W}}{1.5 \text{ V}} = 140 \mu\text{A}$$

ASSESS We expect the current drawn from the battery to be very small since little power is needed to operate a watch.

- 29. INTERPRET** We are to find the voltage at which a device operates, given its resistance and the power it consumes.

DEVELOP Solve Equation 24.8b, $P = V^2/R$, for the voltage V .

EVALUATE Equation 24.8b gives $V = \sqrt{PR} = \sqrt{(1.5 \text{ kW})(35 \Omega)} = 230 \text{ V}$.

ASSESS This is greater than the peak power provided by standard power outlets in the United States, which is not surprising for an electric stove.

- 30. INTERPRET** We want to compare the power consumption of two light bulbs.

DEVELOP We're given the current and voltage, so we'll use Equation 24.7 to find the power: $P = IV$.

EVALUATE The incandescent bulb consumes:

$$P_{\text{inc}} = IV = (0.261 \text{ A})(230 \text{ V}) = 60.0 \text{ W}$$

The LED consumes:

$$P_{\text{LED}} = IV = (34.8 \text{ mA})(230 \text{ V}) = 8.00 \text{ W}$$

At the given electrical cost of 13.5 pence per kWh, we see that for 3 hours of use every day, the yearly costs to run an incandescent bulb and an LED are, respectively:

$$C_{\text{inc/yr}} = (60.0 \text{ W}) \left(\frac{\pounds 0.135}{1 \text{ kWh}} \right) \left(\frac{3 \text{ h}}{\text{day}} \right) \left(\frac{365 \text{ day}}{\text{yr}} \right) = \pounds 8.87$$

$$C_{\text{LED/yr}} = (8.00 \text{ W}) \left(\frac{\pounds 0.135}{1 \text{ kWh}} \right) \left(\frac{3 \text{ h}}{\text{day}} \right) \left(\frac{365 \text{ day}}{\text{yr}} \right) = \pounds 1.18$$

This means that replacing an incandescent bulb with an LED would save $\pounds 7.69$ on the electric bills over a year.

ASSESS The LED consumes approximately 13% of the power consumed by the incandescent bulb, which sounds reasonable. The two bulbs put out the same amount of visible light, but the incandescent one emits a lot of heat (infrared light), which makes it much less efficient.

Section 24.5 Electrical Safety

- 31. INTERPRET** We use the macroscopic version of Ohm's law to find the resistance necessary for the given voltage to drive the given current.

DEVELOP The macroscopic version of Ohm's law is $V = IR$ (Equation 24.5). We are given $V = 40 \text{ V}$ and $I = 120 \text{ mA}$, so we can solve for R .

EVALUATE Inserting the given quantities yields

$$R = \frac{V}{I} = \frac{40 \text{ V}}{120 \text{ mA}} = 333 \Omega$$

ASSESS The resistance of dry skin is much higher than this; so, in dry conditions, this voltage does not pose a threat.

- 32. INTERPRET** We will use the macroscopic version of Ohm's law to find the resistance necessary for a given voltage to drive a specified current.

DEVELOP The macroscopic version of Ohm's law is $V = IR$. We are given $V = 230 \text{ V}$ and $I = 2.5 \text{ mA}$, so we can solve for R .

EVALUATE Inserting the given quantities gives

$$R = \frac{V}{I} = \frac{230 \text{ V}}{2.5 \text{ mA}} = 92 \text{ k}\Omega$$

ASSESS If your skin was wet, your resistance would be much lower and this voltage would pose a serious threat.

- 33. INTERPRET** Given a resistance and voltage, what current would flow? We will use the macroscopic version of Ohm's law, and also estimate whether the resulting current could be felt.

DEVELOP The macroscopic version of Ohm's law is $V = IR$. The resistance is $R = 100 \text{ k}\Omega$, and the voltage is $V = 12 \text{ V}$. The threshold for sensation is listed in Table 24.3 as 0.5–2 mA.

EVALUATE (a) Inserting the given quantities gives a current of

$$I = \frac{V}{R} = \frac{12 \text{ V}}{100 \times 10^3 \Omega} = 0.12 \text{ mA}$$

(b) This current is below the threshold for sensation, and would not be felt.

ASSESS The resistance of human skin varies considerably with moisture. If your hand was wet, the resistance would be lower and the current would be high enough to deliver a noticeable shock.

EXAMPLE VARIATIONS

- 34. INTERPRET** This problem asks us to calculate the current density and the electric field within a conductor carrying an electric current.

DEVELOP Equation 24.4b, $\vec{J} = \vec{E}/\rho$, relates electric field and current density. Here we're given the total current I and the wire diameter, so we can write the current density as $J = I/A$, with A the wire's cross-sectional area. We also need the resistivity of copper from Table 24.1. Then we can solve Equation 24.4b for the electric field.

EVALUATE From the given current and wire dimensions we find a current density and electric field magnitude of

$$J = \frac{I}{A} = \frac{4(200 \text{ A})}{\pi(9.3 \text{ mm})^2} = 2.9 \text{ MA/mm}^2$$

$$E = J\rho = \frac{I\rho}{A} = \frac{4(200 \text{ A})(1.68 \times 10^{-8} \Omega \cdot \text{m})}{\pi(9.3 \text{ mm})^2} = 49 \text{ mV/m}$$

ASSESS This number is a lot smaller than the electric fields we discussed in electrostatic situations. Because copper is such a good conductor, a weak field can drive a substantial current.

- 35. INTERPRET** This problem asks us to calculate the diameter and electric within a conductor carrying an electric current.

DEVELOP Equation 24.4b, $\vec{J} = \vec{E}/\rho$, relates electric field and current density. Here we're given the total current I and the current density, so we can determine the cross-sectional area A using: $J = I/A$. We also need the resistivity of copper from Table 24.1. Then we can solve Equation 24.4b for the electric field.

EVALUATE From the given current and current density we find a diameter and electric field magnitude of

$$J = \frac{4I}{\pi d^2} \rightarrow d = 2\sqrt{\frac{I}{\pi J}} = 2\sqrt{\frac{24 \text{ A}}{\pi(12 \text{ MA/mm}^2)}} = 1.6 \text{ mm}$$

$$E = J\rho = (12 \text{ MA/mm}^2)(1.68 \times 10^{-8} \Omega \cdot \text{m}) = 0.20 \text{ V/m}$$

ASSESS This number is a lot smaller than the electric fields we discussed in electrostatic situations. Because copper is such a good conductor, a weak field can drive a substantial current.

- 36. INTERPRET** This problem asks us to calculate the current density and the electric field within a tube containing an alkaline solution carrying an electric current.

DEVELOP Equation 24.4b, $\vec{J} = \vec{E}/\rho$, relates electric field and current density. Here we're given the total current I and the wire diameter, so we can write the current density as $J = I/A$, with A the wire's cross-sectional area. We are also given the resistivity of the solution, so we can solve Equation 24.4b for the electric field.

EVALUATE From the given current, resistivity, and wire dimensions we find a current density and electric field magnitude of

$$J = \frac{I}{A} = \frac{4(18.7 \text{ A})}{\pi(6.85 \text{ cm})^2} = 5.07 \text{ kA/m}^2$$

$$E = J\rho = \frac{I\rho}{A} = \frac{4(18.7 \text{ A})(0.0466 \Omega \cdot \text{m})}{\pi(6.85 \text{ cm})^2} = 236 \text{ V/m}$$

ASSESS The alkaline solution has a higher resistivity than a typical conductor, so it will require a larger electric field to generate a current.

- 37. INTERPRET** This problem asks us to calculate the diameter and electric field within a region of the solar corona which carries a given current.

DEVELOP Equation 24.4b, $\vec{J} = \vec{E}/\rho$, relates electric field and current density. Here we're given the total current I and the current density, so we can determine the cross-sectional area A using: $J = I/A$. We are also given the resistivity of the cylindrical section of the corona, so we can solve Equation 24.4b for the electric field.

EVALUATE From the given current and current density we find a diameter and electric field magnitude of

$$J = \frac{4I}{\pi d^2} \rightarrow d = 2\sqrt{\frac{I}{\pi J}} = 2\sqrt{\frac{464 \text{ kA}}{\pi(1.8 \text{ mA/m}^2)}} = 2.24 \times 10^4 \text{ m}$$

$$E = J\rho = (1.18 \text{ mA/m}^2)(1.62 \times 10^{-8} \Omega \cdot \text{m}) = 19.1 \text{ pV/m}$$

ASSESS Although the current density does not appear very high in comparison to the other conductors, there is a very large amount of current carried within this large region of the Sun's corona.

- 38. INTERPRET** This problem involves Ohm's law, and we identify the wire as the object in which we want to relate current, voltage, and resistance.

DEVELOP Equation 24.6, $R = \rho L/A$, determines the resistance, so our plan is first to use the resistivity of copper from Table 24.1 in Equation 24.6 and then to use the resulting resistance in Ohm's law (Equation 24.5), $I = V/R$, to find the potential difference.

EVALUATE Table 24.1 gives $\rho = 1.62 \times 10^{-8} \Omega \cdot \text{m}$ for copper, so for the resistance we get

$$R = \frac{\rho L}{A} = \frac{(1.62 \times 10^{-8} \Omega \cdot \text{m})(1.5 \text{ m})}{\pi(0.255 \text{ mm})^2} = 0.12 \Omega$$

Then Ohm's law gives the voltage: $V = IR = (3.5 \text{ A})(0.12 \Omega) = 0.43 \text{ V}$.

ASSESS A wire carrying a large amount of current needs to have a very low resistance so the voltage across the wire remains low.

- 39. INTERPRET** This problem involves Ohm's law, and we identify the wire as the object in which we want to relate current, voltage, and resistance.

DEVELOP Equation 24.6, $R = \rho L/A$, determines the resistance, and Ohm's law (Equation 24.5), $I = V/R$ relates the current, voltage, and resistance. Our plan is first to solve for the resistivity in Equation 24.6 and then to use the given potential difference, current, and wire dimensions to determine the material of the wire by comparing the resistivity to those found in Table 24.1.

EVALUATE Using the two expressions we can express the resistivity as

$$R = \frac{\rho L}{A} = \frac{V}{I} \rightarrow \rho = \frac{AV}{LI} = \frac{\pi(0.320 \text{ mm})^2(235 \text{ mV})}{(2.25 \text{ m})(1.27 \text{ A})} = 2.65 \times 10^{-8} \Omega \cdot \text{m}$$

Thus, the wire is made of aluminum. If the wire were made of copper, with a resistivity of $1.62 \times 10^{-8} \Omega \cdot \text{m}$, the current in the wire would be equal to 2.00 A.

ASSESS For the given potential and dimensions of the wire, a lower resistivity means a higher current can pass through the wire.

- 40. INTERPRET** This problem involves Ohm's law, and we identify the electrolyzer tube in Problem 24.36 as the object in which we want to relate current, voltage, and resistance.

DEVELOP Equation 24.6, $R = \rho L/A$, determines the resistance, and Ohm's law (Equation 24.5), $I = V/R$ relates the current, voltage, and resistance. We can use these expressions to relate the resistance (and thus the resistivity and dimensions of the tube), to the current and potential of the tube.

EVALUATE Using the two expressions we can express the length of the tube as

$$R = \frac{\rho L}{A} = \frac{V}{I} \rightarrow L = \frac{AV}{\rho I} = \frac{\pi(3.425 \text{ cm})^2(162 \text{ V})}{(0.0466 \Omega \cdot \text{m})(18.7 \text{ A})} = 68.5 \text{ cm}$$

ASSESS We could have also found this length by using the electric field found in Problem 24.36 since $L = V/E = 68.5 \text{ cm}$.

- 41. INTERPRET** This problem involves Ohm's law, and we identify the region between Io and Jupiter the "object" in which we want to relate current, voltage, and resistance. We will treat the region as a cylindrical resistor.

DEVELOP Equation 24.6, $R = \rho L/A$, determines the resistance, and Ohm's law (Equation 24.5), $I = V/R$ relates the current, voltage, and resistance. Our plan is first to solve for the resistivity in Equation 24.6 and then to use the given potential difference, current, and wire dimensions to determine which material found in Table 24.1 our result most closely resembles.

EVALUATE Using the two expressions we can express the resistivity as

$$R = \frac{\rho L}{A} = \frac{V}{I} \rightarrow \rho = \frac{AV}{LI} = \frac{\pi(2\text{ Mm})^2(500\text{ kV})}{(600\text{ Mm})(5\text{ MA})} = 2 \times 10^3 \Omega \cdot \text{m}$$

Thus, the region most closely resembles silicon, which has a resistivity of $3 \times 10^3 \Omega \cdot \text{m}$.

ASSESS Although the amount of current driven between the two bodies is quite large, we find that the resistivity of the region most closely resembles that of a semiconductor.

PROBLEMS

- 42. INTERPRET** This problem involves finding the average current for a given time interval and the number of charges that can pass through given a current and a time interval.

DEVELOP The average current is given by Equation 24.1a, which may be written as

$$\bar{I} = \frac{\Delta Q}{\Delta t} = \frac{\sum I_i \Delta t_i}{\Delta t}$$

The number of singly charged ions passing through the channel while current is flowing is $N = \Delta Q/e$.

EVALUATE (a) The average current is

$$\bar{I} = \frac{\sum I_i \Delta t_i}{\Delta t} = \frac{(2.4\text{ pA})(0.2\Delta t)}{\Delta t} = 0.48\text{ pA}$$

(b) The number of ions is

$$N = \frac{\Delta Q}{e} = \frac{I \Delta t}{e} = \frac{(2.4\text{ pA})(1.0\text{ ms})}{(1.6 \times 10^{-19}\text{ C})} = 1.5 \times 10^4$$

ASSESS This is a very small current. Nevertheless, there exists instrumentation that can measure current down to the pico-ampere range.

- 43. INTERPRET** In this problem, we are asked to compare the current density in a light bulb filament and in the wire that supplies electricity to the bulb.

DEVELOP The current density is just current divided by area. The same amount of current flows through the filament and the wire; only the area changes.

EVALUATE (a) For the filament, the current density is:

$$J = \frac{I}{A} = \frac{0.326\text{ A}}{\pi(\frac{1}{2}0.046\text{ mm})^2} = 196\text{ A/mm}^2$$

(b) For the 1.5-mm^2 cross-sectional area wire, the current density is:

$$J = \frac{I}{A} = \frac{0.326\text{ A}}{1.5\text{ mm}^2} = 0.217\text{ A/mm}^2$$

ASSESS The thinner filament has the higher current density, as we would expect.

- 44. INTERPRET** This problem requires us to find the total current in a film, given the current density and the dimensions of the film.

DEVELOP Since current density J is current per unit area (see Example 24.2), the current is $I = JA$ (assuming the current density is perpendicular to the cross-sectional area of the film).

EVALUATE Substituting the values given in the problem statement, we find the current to be

$$I = JA = (4.82 \times 10^5\text{ A/m}^2)(1.2 \times 10^{-4}\text{ m})(1.85 \times 10^{-6}\text{ m}) = 107\text{ }\mu\text{A}$$

ASSESS The current density 0.68 MA/m^2 is approximately the maximum safe current density in typical household wiring.

- 45. INTERPRET** This problem involves two wires of different radii, each carrying the same current I . Given the density of charge carriers in each, we are to find the drift speed and the current density between wires.

DEVELOP Apply Equation 24.3 to each wire, and take the ratio to find the ratio of the drift speeds, using the fact that $I = JA$ and we are given $A_{\text{Al}} = 4A_{\text{Cu}}$. The same strategy may be used to find the ratio of the current densities.

EVALUATE Equation 24.3 gives

$$\frac{I_{\text{Cu}}}{I_{\text{Al}}} = 1 = \frac{J_{\text{Cu}}A_{\text{Cu}}}{J_{\text{Al}}A_{\text{Al}}} = \frac{J_{\text{Cu}}A_{\text{Cu}}}{J_{\text{Al}}(4A_{\text{Cu}})} = \frac{n_{\text{Cu}}e v_{\text{d,Cu}}}{4n_{\text{Al}}e v_{\text{d,Al}}}$$

$$\frac{v_{\text{d,Cu}}}{v_{\text{d,Al}}} = 4 \left(\frac{n_{\text{Al}}}{n_{\text{Cu}}} \right) = 4 \left(\frac{2.1 \times 10^{29}}{1.1 \times 10^{29}} \right) = 7.6$$

(b) The same equation also gives $J_{\text{Cu}}A_{\text{Cu}}/J_{\text{Al}}A_{\text{Al}} = 1$, or $J_{\text{Cu}}/J_{\text{Al}} = A_{\text{Al}}/A_{\text{Cu}} = 4$.

ASSESS Thus, the current density is four times greater in copper than in aluminum. Which wire would you expect to heat up faster for the same current? This is the fundamental concept of a fuse.

- 46. INTERPRET** In this problem, we are given the microscopic parameters for a circuit composed of three components and asked to calculate the drift speed of charge carriers in each component.

DEVELOP The drift speed of a charge can be calculated using either Equation 24.2 or Equation 24.3:

$$v_{\text{d}} = \frac{I}{nAq} = \frac{J}{nq}$$

EVALUATE In the copper wire, the drift speed is

$$v_{\text{d}} = \frac{I}{n e A} = \frac{100 \times 10^{-3} \text{ A}}{(1.1 \times 10^{29} \text{ m}^{-3})(1.6 \times 10^{-19} \text{ C}) \left(\frac{1}{4} \pi \right) (0.10 \times 10^{-3} \text{ m})^2} = 0.72 \text{ mm/s}$$

In the solution, the positive and negative ions have equal charge magnitudes, number, and current densities, so

$J = n_+(2e)v_{\text{d}} + n_-(2e)(-v_{\text{d}}) = 4nev_{\text{d}}$. Thus, with uniform current density, $J = I/A$, the drift speed is

$$v_{\text{d}} = \frac{J}{4ne} = \frac{I}{4neA} = \frac{100 \times 10^{-3} \text{ A}}{4(6.5 \times 10^{23} \text{ m}^{-3})(1.6 \times 10^{-19} \text{ C}) \left(\frac{1}{4} \pi \right) (1.0 \times 10^{-2} \text{ m})^2} = 3.1 \text{ mm/s}$$

Similarly, in the vacuum tube, we have

$$v_{\text{d}} = \frac{I}{n e A} = \frac{100 \times 10^{-3} \text{ A}}{(2.1 \times 10^{16} \text{ m}^{-3})(1.6 \times 10^{-19} \text{ C}) \left(\frac{1}{4} \pi \right) (1.0 \times 10^{-3} \text{ m})^2} = 3.8 \times 10^7 \text{ m/s}$$

ASSESS Since the drift speed v_{d} is inversely proportional to the number density n , it is greatest in the vacuum tube (by some 10 orders of magnitude!) and smallest in the copper wire.

- 47. INTERPRET** For this problem, we are given the current as a function of time and are asked to find the current of a 5.0-s interval.

DEVELOP Integrate Equation 24.1b from $t = 0.0$ to $t = 5.0$ s, with $I(t)$ as given in the problem statement.

EVALUATE Performing the integration gives

$$q = \int_{0.0}^{5.0} I(t) dt = \int_{0.0}^{5.0} (60t + 200t^2 + 4.0t^3) dt = \left[30t^2 + \frac{200}{3}t^3 + 1.0t^4 \right]_{0.0}^{5.0} = \left(30 + \frac{1000}{3} + 25 \right) (25) \text{ nC} = 9.7 \text{ } \mu\text{C}$$

ASSESS Because the formula for I is in nA, we get nC when we multiply by seconds.

- 48. INTERPRET** This problem involves using the macroscopic version of Ohm's law to find the current density, the electric field in the wire, and the voltage between two ends of a gold wire for a given current.

DEVELOP For a current carrying wire, the corresponding current density can be obtained from: $I = JA$ where A is the cross-sectional area of the wire ($A = \pi r^2/4$). Equation 24.4b, $J = E/\rho$ can then be used to find the electric field across the wire, where ρ is the resistivity of the wire ($\rho = 2.24 \times 10^{-8} \Omega \cdot \text{m}$ for gold). Finally, we can determine the potential difference across the wire's ends by expressing the resistance using Equation 24.6: $R = \rho L/A$, where L is the length of the wire, and calculating $V = IR$.

EVALUATE (a) Inserting the values given in the problem statement, we find the current density to be

$$J = \frac{I}{A} = \frac{4I}{\pi d^2} = \frac{4(0.600 \text{ A})}{\pi(2.54 \times 10^{-5} \text{ m})^2} = 1.2 \text{ GA/m}^2$$

(b) The electric field is then equal to

$$E = J\rho = (1.2 \times 10^9 \text{ A/m}^2)(2.24 \times 10^{-8} \Omega \cdot \text{m}) = 27 \text{ V/m}$$

(c) Finally, we find the voltage between the ends of the wire are equal to

$$V = IR = I \frac{\rho L}{A} = (0.600 \text{ A}) \frac{4(2.24 \times 10^{-8} \Omega \cdot \text{m})(1.27 \times 10^{-3} \text{ m})}{\pi(2.54 \times 10^{-5} \text{ m})^2} = 34 \text{ mV}$$

Here we have used the fact that $1.0 \text{ mil} = 2.54 \times 10^{-5} \text{ m}$.

ASSESS The power associated with this current carrying wire is: $P = IV = 20 \text{ mW}$.

49. **INTERPRET** Given the current and the cross-sectional area of a copper wire, we are to find the current density and the electric field.

DEVELOP The current density is $J = I/A$. From Table 24.1, the resistivity is $\rho = 1.68 \times 10^{-8} \Omega \cdot \text{m}$, which we can use in Equation 24.4b to find the electric field.

EVALUATE (a) For a wire carrying uniform current density,

$$J = \frac{I}{A} = \frac{20 \text{ A}}{2.5 \times 10^{-6} \text{ m}^2} = 8.0 \times 10^6 \text{ A/m}^2$$

(b) The electric field is $E = \rho J = (1.68 \times 10^{-8} \Omega \cdot \text{m})(8.0 \times 10^6 \text{ A/m}^2) = 134 \text{ mV/m}$.

ASSESS This is a rather small electric field. This is not surprising because copper is a good conductor, so the charges react quickly in an attempt to cancel out any electric field in the material.

50. **INTERPRET** In this problem, we are asked to compare the voltages across two wires of equal dimensions with one made of silver and the other of iron, given that they both carry the same current.

DEVELOP The resistance of a uniform wire of Ohmic material is given by Equation 24.6: $R = \rho L/A$. Therefore, for equal L , A , and I , the ratio of the voltages is

$$\frac{V_{\text{Fe}}}{V_{\text{Ag}}} = \frac{IR_{\text{Fe}}}{IR_{\text{Ag}}} = \frac{\rho_{\text{Fe}}}{\rho_{\text{Ag}}}$$

EVALUATE Using Table 24.1 for resistivities, we obtain

$$\frac{V_{\text{Fe}}}{V_{\text{Ag}}} = \frac{\rho_{\text{Fe}}}{\rho_{\text{Ag}}} = \frac{9.71 \times 10^{-8} \Omega \cdot \text{m}}{1.59 \times 10^{-8} \Omega \cdot \text{m}} = 6.11$$

ASSESS Since iron has higher resistivity than silver, for the same length, area, and current, the voltage across the iron wire is higher.

51. **INTERPRET** We are given the dimensions and electrical characteristics of a material (i.e., voltage and current) and are asked to identify the material by matching its resistivity to one from Table 24.1.

DEVELOP For a uniform piece of material, Equations 24.5 and 24.6 imply $\rho = RA/L = VA/IL = V(\frac{1}{4}\pi d^2)/IL$.

EVALUATE Inserting the given quantities gives

$$\rho = \frac{(9 \text{ V})(\frac{1}{4}\pi)(2.0 \text{ mm})^2}{(2.6 \text{ mA})(2.4 \text{ cm})} = 0.453 \Omega \cdot \text{m}$$

which is closest to the resistivity of germanium ($= 0.47 \Omega \cdot \text{m}$) in Table 24.1.

ASSESS This is a useful concept for identifying materials.

- 52. INTERPRET** This problem compares resistances of wires made up of different materials. The microscopic and macroscopic versions of Ohm's law are involved.

DEVELOP The resistance of a uniform wire of Ohmic material is given by Equation 24.6: $R = \rho L/A$. Therefore, the resistance per unit length is

$$\frac{R}{L} = \frac{\rho}{A} = \frac{\rho}{\pi d^2/4}$$

EVALUATE Equal resistance per unit length for copper and aluminum wires imply that

$$\frac{\rho_{\text{Cu}}}{d_{\text{Cu}}^2} = \frac{\rho_{\text{Al}}}{d_{\text{Al}}^2} \Rightarrow \frac{d_{\text{Al}}}{d_{\text{Cu}}} = \sqrt{\frac{\rho_{\text{Al}}}{\rho_{\text{Cu}}}} = \sqrt{\frac{2.65 \times 10^{-8} \Omega \cdot \text{m}}{1.68 \times 10^{-8} \Omega \cdot \text{m}}} = 1.26$$

where we have used Table 24.1 for resistivities.

ASSESS Since $d \propto \rho^{1/2}$, a higher resistivity means a larger diameter wire.

- 53. INTERPRET** You need to specify the maximum length of an extension cord for a power saw. The cord has resistance that will reduce the voltage difference across the power saw's motor.

DEVELOP Let's define 4 points along the current's path; see the figure below. You're told that the voltage across the outlet, ΔV_{14} , is 230 V, and the voltage across the motor, ΔV_{23} , is 225 V.

The copper wires in the extension cord will produce a voltage drop due to their resistance: $\Delta V_{12} = \Delta V_{34} = IR$.

The resistance is given by Equation 24.6: $R = \rho L/A$, where $\rho = 1.68 \times 10^{-8} \Omega \cdot \text{m}$ for copper, A is the area of the wire, and L is the length of the cord. For the voltage differences to be consistent with each other:

$$\Delta V_{14} = \Delta V_{12} + \Delta V_{23} + \Delta V_{34} \rightarrow 2IR = 5 \text{ V}$$

Since the saw draws 13 A, the resistance in one direction of the extension cord is 0.192Ω .

EVALUATE Solving for the length of the cord, we get:

$$L = \frac{RA}{\rho} = \frac{(0.192 \Omega)(1.5 \times 10^{-6} \text{ m}^2)}{1.68 \times 10^{-8} \Omega \cdot \text{m}} = 17.1 \text{ m}$$

Because the cords come in increments of 5 m, the maximum length of the extension cord one can use with the saw is 15 m.

ASSESS We generally tend to ignore the resistance in the wires that carry current to an electric device. But for an extension cord, the long length of the wires means their resistance will have to be accounted for.

- 54. INTERPRET** We're asked to determine how much electricity flows out of a heart pacemaker.

DEVELOP The pacemaker provides a voltage across the heart for a short pulse. The current flowing during a pulse can be found by using Ohm's law: $I = V/R$. The power delivered by a pulse is $P = V^2/R$ (Equation 24.8b), which means the energy delivered is just $\Delta E = P\Delta t$, where Δt is the length of a pulse.

EVALUATE (a) The current flowing from the pacemaker is

$$I = \frac{V}{R} = \frac{6.8 \text{ V}}{550 \Omega} = 12.4 \text{ mA}$$

(b) The energy delivered over a single pulse is

$$\Delta E = \frac{V^2 \Delta t}{R} = \frac{(6.8 \text{ V})^2 (0.68 \text{ ms})}{(550 \Omega)} = 57 \mu\text{J}$$

(c) For the average power, we take the energy per pulse and multiply it by the frequency of pulses, that is, 72 per minute:

$$\bar{P} = \Delta E \cdot f = (57.169 \mu\text{J})(72 / 60 \text{ s}^{-1}) = 68.6 \mu\text{W}$$

ASSESS The average power delivered to the heart is very small; it is more than 1000 times smaller than the power during a single pulse ($P = IV = 84 \text{ mW}$).

- 55. INTERPRET** We are to find the resistance between opposing faces of a rectangular block of gold, given that the opposing faces are all equipotentials (i.e., the electric potential is the same across any given pair of faces).

DEVELOP If opposite faces are equipotentials, the current density is uniform over any parallel cross section. In this case, Equation 24.6 gives $R_1 = \rho L_1 / (L_2 \times L_3)$, where L_1 is the length in the direction of the potential drop and $L_2 \times L_3$ is the cross-sectional area of an equipotential face.

EVALUATE For $L_1 = 0.254 \text{ mm}$, $L_2 = 0.186 \text{ mm}$, and $L_3 = 2.00 \mu\text{m}$, and permutations thereof, we find $R_1 = (2.24 \times 10^{-8} \Omega \cdot \text{m})(0.254 \text{ mm}) / (0.186 \times 0.002 \text{ mm}^2) = 15.3 \text{ m}\Omega$, $R_2 = 8.20 \text{ m}\Omega$, and $R_3 = 948 \text{ n}\Omega$.

ASSESS The greatest resistance is greatest for current traversing the greatest length per unit area.

- 56. INTERPRET** We are to find the instantaneous current and the average current of a pulse produced by a taser, and the effective resistance of the person in contact.

DEVELOP According to the passage described on page 443, the duration of each taser pulse is about $100 \mu\text{s}$, and 19 such pulses could be delivered per second. In addition, we are told that each pulse delivers $100 \mu\text{C}$ of charge to the victim. The definition of an ampere is 1 C/s . Inspecting the units shows that we can get the current by dividing the charge q by the given time Δt over which the pulses are delivered.

EVALUATE (a) With $\Delta t = 100 \mu\text{s}$, we find the instantaneous current to be

$$I = \frac{\Delta q}{\Delta t} = \frac{100 \mu\text{C}}{100 \mu\text{s}} = 1.0 \text{ A}$$

(b) With 19 such pulses per second, we find the average current to be

$$\bar{I} = \frac{\overline{\Delta q}}{\Delta t} = \frac{19(100 \mu\text{C})}{1.0 \text{ s}} = 1.9 \times 10^{-3} \text{ A} = 1.9 \text{ mA}$$

(c) Given that the potential difference across the darts in the pulse is 1200 V , the effective resistance of the victim between the points where the probes make contacts is

$$R = \frac{V}{I} = \frac{1200 \text{ V}}{1.0 \text{ A}} = 1200 \Omega = 1.2 \text{ k}\Omega$$

ASSESS The voltage, pulse shape, and pulse duration are engineered to cause major skeletal muscles to contract involuntarily without affecting the heart muscle and without dangerously strong contractions that would occur at much higher pulse rates. The intent is to effectively immobilize the victim without danger or permanent damage.

- 57. INTERPRET** This problem involves analyzing the performance of a model of Nissan Leaf, an all-electric car.

DEVELOP The time required to charge the battery is given by $\Delta t = U / P$, where $U = 24 \text{ kWh}$ is the energy stored in the battery when fully charged, and P is the charging rate. The current delivered by the fully charged battery is $I = P / V$, where V is the terminal voltage of the battery.

EVALUATE (a) The range, or the longest distance the car can travel without recharging is

$$d = (3.38 \text{ mi/kWh})(24 \text{ kWh}) = 81.1 \text{ mi}$$

(b) For the two charging modes, the times required are:

$$t_1 = \frac{24 \text{ kWh}}{6.3 \text{ kW}} = 3.8 \text{ h}$$

$$t_2 = \frac{24 \text{ kWh}}{44 \text{ kW}} = 0.55 \text{ h} = 33 \text{ min}$$

(c) With $1 \text{ hp} = 746 \text{ W}$, the current delivered by the fully charged battery is

$$I = \frac{P}{V} = \frac{(107 \text{ hp})(746 \text{ W/hp})}{394 \text{ V}} = 203 \text{ A}$$

ASSESS Electric cars are ideal for a short commute. Our calculation indicates that you can drive the Nissan Leaf for about 80 miles without charging.

- 58. INTERPRET** This problem involves using electric heater to boil water. Electric energy is converted to thermal energy. By analyzing the data of different currents through the heater versus the times required to raise the water temperature by 10°C , we can deduce the heater's resistance.

DEVELOP Combining Equations 6.15 for the average power and 16.3 that relates thermal energy to temperature change, the power required to bring the water to its boiling point is

$$P = \frac{\Delta Q}{\Delta t} = \frac{m_w c_w \Delta T}{\Delta t}$$

By applying Equation 24.8a, $P = I^2 R$, which is applicable for Ohmic devices, we obtain

$$\Delta t = \frac{m_w c_w \Delta T}{P} = \frac{m_w c_w \Delta T}{I^2 R} = \left(\frac{m_w c_w \Delta T}{R} \right) \frac{1}{I^2}$$

Thus, plotting Δt versus $1/I^2$ will give a straight line with slope $\frac{m_w c_w \Delta T}{R}$. From the value of the slope, we can find the resistance of the heater.

EVALUATE The plot is shown below.

The slope of the best-fit line is 1686.6 (in SI units), from which we find the resistance to be

$$R = \frac{m_w c_w \Delta T}{\text{slope}} = \frac{(0.5)(4184)(10)}{1686.6} = 12.4 \Omega$$

ASSESS A resistance of 12Ω is typical for an electric heater. Note that besides the power supplied to heat up water, additional power is also needed to compensate for any power lost to the surroundings or cup, plus that used by the heater itself. All these factors have been neglected in this problem.

- 59. INTERPRET** We are asked to calculate the power associated with the electric current between Jupiter and its moon Io, and compare with human consumption.

DEVELOP We are told that the current is 5 MA and the voltage is about 500 kV. We use Equation 24.7 to find the power: $P = IV$.

EVALUATE Substituting the values given, we find the power to be

$$P = IV = (5.0 \times 10^6 \text{ A})(5.00 \times 10^5 \text{ V}) = 2.5 \times 10^{12} \text{ W} = 2.5 \text{ TW}$$

ASSESS This rate, 2.5 TW, is about the same as the rate at which humankind consumes.

- 60. INTERPRET** We are asked to show that the power dissipated per unit volume is given by $J^2 \rho$.

DEVELOP Consider a small volume element in the material, ΔV , where the current density is $\vec{J} = nq\vec{v}_d$, where \vec{v}_d is the drift velocity. The electric field does work on each charge carrier at a rate equal to $\vec{F}_e \cdot \vec{v}_d = q\vec{E} \cdot \vec{v}_d$, so the total power is this times the number of charge carriers in ΔV :

$$\Delta P = Nq\vec{E} \cdot \vec{v}_d = (n\Delta V)q\vec{E} \cdot \vec{v}_d = \Delta V(\vec{E} \cdot \vec{J}).$$

The proof can be completed using Ohm's law: $\vec{J} = \sigma\vec{E} = \vec{E} / \rho$.

EVALUATE Combining the above expressions leads to

$$\Delta P = \Delta V(\vec{E} \cdot \vec{J}) = \Delta V(\rho J^2)$$

from which we readily obtain

$$\frac{\Delta P}{\Delta V} = \rho J^2$$

ASSESS This power is transformed into random thermal motion of the charge carriers and ions of the material, and is referred to as joule heat; ρJ^2 is the rate of joule heating per unit volume of material.

- 61. INTERPRET** This problem involves raising water temperature via joule heating, with electric energy is converting to thermal energy.

DEVELOP As shown in the previous problem, joule heating per unit volume is given by ρJ^2 . Thus, the power expended to heating the water is

$$P = \frac{\Delta Q}{\Delta t} = \rho J^2 \Delta V = \frac{m_w c_w \Delta T}{\Delta t}$$

where we take the specific heat of seawater to be $c_w = 4.0 \text{ J/g} \cdot ^\circ\text{C}$.

EVALUATE The time required is

$$\Delta t = \frac{m_w c_w \Delta T}{\rho J^2 \Delta V} = \frac{\rho_m c_w \Delta T}{\rho J^2} = \frac{(1.025 \text{ g/cm}^3)(4.0 \text{ J/g} \cdot ^\circ\text{C})(20^\circ\text{C} - 15^\circ\text{C})}{(22 \Omega \cdot \text{cm})(75 \times 10^{-3} \text{ A/cm}^2)^2} = 166 \text{ s} = 2.8 \text{ min}$$

ASSESS Joule heating is proportional to resistivity ρ . The greater the ρ , the less time it takes to heat up the water.

- 62. INTERPRET** You want to check if your car battery is working properly by measuring the resistance between the battery and the starter.

DEVELOP By Ohm's law, the resistance is the voltage divided by the current.

EVALUATE From your measurements,

$$R = \frac{V}{I} = \frac{4.2 \text{ V}}{125 \text{ A}} = 34 \text{ m}\Omega$$

The resistance is far above normal.

ASSESS Corrosion is due to chemical reactions that change the metals at the contacts on the battery. Metal compounds (such as metal sulfates and metal oxides) are typically poor conductors, so the resistance in the battery connections increases.

- 63. INTERPRET** This problem involves the dependence of resistance and power dissipation on the geometry of the material. We are to find the diameters of resistors given their length is the same and the same voltage is applied across both.

DEVELOP Equation 24.6, $R = \rho L/A$, relates the resistance of a material to its geometry (length and cross-sectional area). With a fixed voltage, the power dissipated is given by Equation 24.8b, $P = V^2/R$. Thus, we see that at the same voltage, the ratio of the power dissipated is the inverse of the ratio of the resistances, which, in turn, goes as the inverse of the square of the ratio of the diameters:

$$\frac{P_1}{P_2} = \frac{V^2/R_1}{V^2/R_2} = \frac{R_2}{R_1} = \frac{\rho L/A_2}{\rho L/A_1} = \frac{A_1}{A_2} = \frac{\pi d_1^2/4}{\pi d_2^2/4} = \left(\frac{d_1}{d_2}\right)^2$$

EVALUATE From the equation above, we see that if $P_1 = 2P_2$, then $d_1 = \sqrt{2}d_2$.

ASSESS Our result shows that power dissipated increases with the area, or the square of the diameter, $P \propto A \propto d^2$.

- 64. INTERPRET** This problem concerns the power loss along a wire that supplies electric power to a high-speed train.

DEVELOP The amount of current needed to meet the train's power needs is given by Equation 24.7, $I = P_{\text{train}}/V$. We'll assume that no matter how far the train has gone, the voltage between the wire and the track is always 22

kV. But the farther the train goes, the farther the current travels down the wire. This will lead to power loss given by Equation 24.8a, $P_{\text{loss}} = I^2 R$, where the resistance increases linearly with distance: $R = \lambda x$, $\lambda = 15 \text{ m}\Omega / \text{km}$.

EVALUATE To ensure that P_{loss} is less than 3% of the train's power use, the distance traveled must be less than

$$x \leq \frac{0.03 P_{\text{train}}}{\lambda I^2} = \frac{0.03 V^2}{\lambda P_{\text{train}}} = \frac{0.03 (22 \text{ kV})^2}{(15 \text{ m}\Omega / \text{km})(6000 \text{ hp})} \left[\frac{1 \text{ hp}}{746 \text{ W}} \right] = 216 \text{ km}$$

ASSESS This seems like a reasonable distance for a train to travel. Beyond this distance, the train can presumably obtain its electricity from a different power plant that might be closer. Note that the maximum distance is proportional to the voltage squared. This implies that power loss can be reduced by increasing the potential difference between the wire and the track.

- 65. INTERPRET** This problem is about using electric power to do mechanical work.

DEVELOP If there are no losses, the electrical power supplied to the motor, $P_{\text{in}} = IV$, must equal the mechanical power expended in lifting the weight, $P_{\text{out}} = Fv$ (see Equation 6.19).

EVALUATE With $P_{\text{in}} = P_{\text{out}}$, the current is

$$I = \frac{Fv}{V} = \frac{(20 \text{ N})(30 \text{ cm/s})}{6.0 \text{ V}} = 1.0 \text{ A}$$

ASSESS In reality, the motor will not be 100% efficient. So the current drawn will be somewhat higher than 1.0 A.

- 66. INTERPRET** This problem involves a circuit with a given resistance and voltage and for which we are to find the current and the fraction of power lost over the circuit.

DEVELOP To find the current, apply Equation 24.7, $P_{\text{out}} = IV$. The fraction of power lost is that due to the resistance, $P_{\text{loss}} = I^2 R$ (Equation 24.8a) divided by the power supplied P_{out} .

EVALUATE (a) Inserting the given quantities gives $I = P_{\text{out}}/V = (1000 \times 10^6 \text{ W})/115 \text{ kV} = 8.70 \text{ kA}$.

(b) The power loss in the transmission line is $P_{\text{loss}} = I^2 R_{\text{line}} = (8.70 \text{ kA})^2 (0.050 \Omega/\text{km} \times 40 \text{ km}) = 151 \text{ MW}$, which is $151/1000 \times 100\% = 15.1\%$ of the power supplied.

ASSESS The power lost in transmission is quite significant.

- 67. INTERPRET** You are looking to save money on utility costs by comparing copper to aluminum wires.

DEVELOP You're given the specifications for the resistance per unit length along the power line. From Equation 24.6: $R/L = \rho/A$, where the resistivity of copper and aluminum are $\rho_{\text{Cu}} = 1.68 \times 10^{-8} \Omega \cdot \text{m}$ and $\rho_{\text{Al}} = 2.65 \times 10^{-8} \Omega \cdot \text{m}$, respectively. This allows you to specify the cross-sectional area, A , of the wire. Since the mass per length is $m/L = \eta A$, where η is the mass density for either copper or aluminum, the cost per unit length will be

$$C/L = (C/m)(m/L) = \frac{(C/L)\eta\rho}{(R/L)}$$

where C/m is cost per kg of the material.

EVALUATE The cost per length of copper wire is

$$C_{\text{Cu}}/L = \frac{(\$6.86/\text{kg})(8.9 \text{ g/cm}^3)(1.68 \times 10^{-8} \Omega \cdot \text{m})}{(50 \text{ m}\Omega/\text{km})} = \$20.51/\text{m}$$

The cost per length of aluminum wire is

$$C_{\text{Al}}/L = \frac{(\$2.23/\text{kg})(2.7 \text{ g/cm}^3)(2.65 \times 10^{-8} \Omega \cdot \text{m})}{(50 \text{ m}\Omega/\text{km})} = \$3.19/\text{m}$$

Clearly, the aluminum is more economical.

ASSESS Copper is a better conductor, so the required diameter of the wire ($d = 2.1 \text{ cm}$) is smaller than that for aluminum ($d = 2.6 \text{ cm}$). But aluminum is lighter and costs less per kilo, so it would save money to use aluminum wires.

- 68. INTERPRET** For this problem, we are to find the current required by an electric motor with the given efficiency and voltage to deliver the power necessary to lift a mass at the given rate.

DEVELOP From Equation 24.7, the electrical power supplied to the motor is $P_{\text{in}} = IV$. The power required by the mechanical lifting is given by Equation 6.19, $P_{\text{mech}} = Fv$. With 90% efficiency, the mechanical power expended in lifting the weight is $P_{\text{out}} = P_{\text{mech}} = Fv = 0.90P_{\text{in}} = 0.90IV$.

EVALUATE Thus, the current drawn is

$$I = \frac{Fv}{0.90V} = \frac{(200 \text{ N})(3.4 \text{ m/s})}{0.90(240 \text{ V})} = 3.1 \text{ A}$$

ASSESS The less efficiently the motor operates, the more the current that must be drawn to supply the required power.

- 69. INTERPRET** This problem involves a nonuniform current density in a metal bar. We are given the dimensions of the bar and are to find the total current in the bar.

DEVELOP Use the coordinate system given below in the figure. The current density in the bar is

$\vec{J} = (0.10 \text{ A/cm}^2)(x/10 \text{ cm})\hat{k}$. The cross section can be divided into strips of area $d\vec{A} = (5.0 \text{ cm}) dx\hat{k}$ (over which \vec{J} is constant), so we can integrate over x to find the total current:

$$I = \int_x \vec{J} \cdot d\vec{A}$$

EVALUATE Performing the integration gives

$$\begin{aligned} I &= \int_x \vec{J} \cdot d\vec{A} = \int_0^{10 \text{ cm}} (0.010 \text{ A/cm}^2)(x) (5.0 \text{ cm}) dx \\ &= (0.050 \text{ A/cm}^2) \frac{1}{2} (10 \text{ cm})^2 = 2.5 \text{ A} \end{aligned}$$

ASSESS This is quite a significant current!

- 70. INTERPRET** This problem involves using electric power to boil water. Electric energy is converted to thermal energy, and we are to find the power required to heat the water in the given time and, from the power, find the heater's resistance.

DEVELOP Combining Equations 6.15 for the average power and 16.3 that relates thermal energy to temperature change, the power required to bring the water to its boiling point is

$$\bar{P} = \frac{\Delta Q}{\Delta t} = \frac{m_w c_w \Delta T}{\Delta t}$$

We can then apply Equation 24.8b, $P = V^2 / R$, which is applicable for Ohmic devices, to find the resistance of the heater.

EVALUATE (a) Substituting the values given in the problem, we find the power is

$$\bar{P} = \frac{m_w c_w \Delta T}{\Delta t} = \frac{(250 \text{ mL})(1.0 \text{ g/mL})[4.184 \text{ J/(g} \cdot \text{K)}](100^\circ\text{C} - 10^\circ\text{C})}{89 \text{ s}} = 1.1 \text{ kW}$$

(b) With $P = V^2 / R$, the heater's resistance is

$$R = \frac{V^2}{P} = \frac{(230 \text{ V})^2}{1.06 \text{ kW}} = 50 \Omega$$

ASSESS Besides the power supplied to heat up water, additional power is also needed to compensate for any power lost to the surroundings or cup, plus that used by the heater itself. All these factors have been neglected in this problem.

- 71. INTERPRET** For this problem, we are to find an expression for the resistivity through the solution with resistivity ρ from the cylinder side to the center disk.

DEVELOP Consider a concentric cylindrical surface S , of radius r and height h , between the two metal electrodes. S completely surrounds the inner disk, so the current flowing (assumed from the center to the sides) is

$$I = \int_S \vec{J} \cdot d\vec{A} = \int_S (\vec{E}/\rho) \cdot d\vec{A}$$

for an Ohmic solution. If the electrodes behave like perfect conductors ($\rho_{\text{metal}} = 0$) they are essentially equipotentials, and the electric field in the solution has cylindrical (line) symmetry. (There are no fringing fields because outside the solution, the current density is zero.) Thus, without changing the integral, flat circular surfaces above and below may be added to close the surface S , so that

$$\rho I = \int_S \vec{E} \cdot d\vec{A}$$

This integral is the same as the one appearing in Gauss's law for two conductors in an identical configuration, as in Example 21.5. Thus,

$$\rho I = \int_S \vec{E} \cdot d\vec{A} = \frac{2\pi h V}{\ln(b/a)}$$

where $V = V_a - V_b$ is the potential difference and we used h instead of L for the length. Comparing this with the macroscopic version of Ohm's law (Equation 24.5) $V = IR$, we can solve for the resistivity ρ .

EVALUATE A comparison of this with Ohm's law, $V = IR$, shows that the resistance between the electrodes is

$$R = \frac{\rho \ln(b/a)}{2\pi h}$$

ASSESS In terms of the capacitance of the same configuration of electrodes with air between the electrodes,

$$q/\epsilon_0 = CV/\epsilon_0 = \rho I = \rho(V/R), \text{ or } R = \rho\epsilon_0/C$$

This relation holds for electrodes of arbitrary shape.

- 72. INTERPRET** We are to find the current in a particle beam, given its current density as a function of the beam radius. The beam is circular, has a current density J_0 at the center, and the current density falls to half that value at the edge.

DEVELOP Integrate the current density over the beam to find the total current. From the problem statement, we can express the current density as a function of radius as

$$J(r) = J_0 - \frac{J_0 r}{2a}$$

$$R = \int dR = \int_a^b \frac{\rho \left(\frac{L}{b-a} dr \right)}{\pi r^2} = \frac{\rho L}{\pi(b-a)} \left[\frac{-1}{r} \right]_a^b = \frac{\rho L}{\pi ab}$$

To find the total current, integrate over circular rings of radius r , each of which has area $dA = 2\pi r dr$.

EVALUATE Performing the integration gives

$$dI = J dA$$

$$\begin{aligned} I &= \int_0^a J(r) dA = 2\pi J_0 \int_0^a \left(1 - \frac{r}{2a} \right) r dr \\ &= 2\pi J_0 \left(\frac{r^2}{2} - \frac{r^3}{6a} \right) \Big|_0^a = \frac{2}{3} J_0 \pi a^2 \end{aligned}$$

ASSESS The beam current is two-thirds as much as it would be if the current density was constant.

73. INTERPRET You want to find the steepest hill that a hybrid car can climb using only its battery.

DEVELOP The maximum power that the battery can supply is given by $P_{\max} = I_{\max} V$. If all this power is used to propel the car forward, then the force will be equal to the power divided by the velocity: $F = P_{\max} / v$ (recall Equation 6.19). If we neglect wind resistance, this force must be equal and opposite to the component of the gravitational force that is parallel to the slope of the incline, $mg \sin \theta$.

EVALUATE Solving for the angle of the incline gives:

$$\theta = \sin^{-1} \left(\frac{I_{\max} V}{mgv} \right) = \sin^{-1} \left(\frac{(190 \text{ A})(360 \text{ V})}{(1200 \text{ kg})(9.8 \text{ m/s}^2)(68 \text{ km/h})} \right) = 17.9^\circ = 18^\circ$$

ASSESS It's rare that one encounters a slope this steep. But in a real situation, you would have to account for not all of the battery's power being used to turn the wheels. Moreover, the drag from wind resistance will reduce the car's speed for a given battery output.

74. INTERPRET We explore the effects of a brownout on an electrical network.

DEVELOP We first consider conductors whose resistance is independent of temperature.

EVALUATE A 10% reduction in voltage will result in a corresponding 10% drop in the current through a conductor whose resistance is essentially constant.

The answer is **(a)**.

ASSESS This will be true for any conductor that obeys Ohm's law.

75. INTERPRET We explore the effects of a brownout on an electrical network.

DEVELOP We will use the fact that the current density ($J = I / A$) decreases during a brownout.

EVALUATE The current density is related to the electric field by Equation 24.4b: $E = \rho J$, so the electric field strength should decrease with the current density. The current density is also related to the number of charge carriers and the drift speed through Equation 24.3: $J = nqv_d$. The number of free electrons does not vary in conductors under normal conditions. Therefore, the drift speed must fall when the current density decreases. Finally, the number of electron collisions depends primarily on the temperature.

The answer is **(a)**.

ASSESS Another way to think of this is that the electric field is directly related to the voltage: $E = dV / dx$ in the one-dimensional case. So a drop in voltage corresponds to a drop in the electric field. Moreover, the electric field provides a force on the charges that results in the drift velocity.

76. INTERPRET We explore the effects of a brownout on an electrical network.

DEVELOP The power dissipated in conductors with constant resistance can be written as $P = IV$, $P = V^2 / R$ or $P = I^2 R$.

EVALUATE No matter which expression we use for the power, there will be a factor of $0.9^2 = 0.81$, which means the power will decrease by about 20%.

The answer is **(b)**.

ASSESS This power reduction is what customers will notice, as their light bulbs will be about 20% dimmer than usual (but see the next problem).

77. INTERPRET We explore the effects of a brownout on an electrical network.

DEVELOP The temperature of the resistor in a light bulb or a stove top should be proportional to the power being dissipated. Since we've just argued in the previous problem that the power decreases during a brownout, the temperature in these resistors should be lower than normal periods of electricity supply.

EVALUATE As the problem states, the resistance scales with the temperature, so these devices should have slightly higher current going through them than if their resistance were constant. In other words, their current decreases by less than 10%.

The answer is **(c)**.

ASSESS This temperature dependence reflects the fact that at higher temperatures there will be more electron collisions. This reduces the net flow of charge in the direction of the applied electric potential.
