Section 29.2 Ambiguity in Ampère's Law

- 11. INTERPRET** In this problem, we are asked to find the displacement current through a surface.

DEVELOP As shown in Equation 29.1, Maxwell's displacement current is

$$I_d = \epsilon_0 \frac{d\Phi_E}{dt} = \epsilon_0 \frac{d(EA)}{dt} = \epsilon_0 A \frac{dE}{dt}$$

EVALUATE The above equation gives

$$I_d = \epsilon_0 A \frac{dE}{dt} = [8 \cdot 85 \times 10^{-12} \text{ C}^2 / (\text{N} \cdot \text{m}^2)] (1.6 \text{ cm}^2) [1.0 \text{ V} / (\text{m} \cdot \mu\text{s})] = 1.4 \text{ nA}$$

ASSESS Displacement current arises from changing electric flux and has units of amperes (A), just like ordinary current.

- 12. INTERPRET** This problem involves finding the displacement current across a parallel-plate capacitor, given the rate at which the voltage is changing.

DEVELOP The electric field is approximately uniform in the capacitor, so $\Phi_E = EA = (V/d)A$. Differentiate this with respect to time to find the displacement current.

EVALUATE The displacement current is

$$I_d = \epsilon_0 \partial \Phi_E / \partial t = \left(\epsilon_0 \frac{A}{d} \right) \frac{dV}{dt} = \frac{(8 \cdot 85 \times 10^{-12} \text{ F/m})(13 \text{ cm})^2 (220 \text{ V/ms})}{0.50 \text{ cm}} = 6.6 \mu\text{A}$$

ASSESS The units of the displacement current work out to be (with the help of Appendix B)

$$\frac{(\text{F/m})(\text{m})^2 (\text{V/s})}{\text{m}} = \frac{(\text{m}^{-2} \cdot \text{kg}^{-1} \cdot \text{s}^4 \cdot \text{A}^2 / \text{m})(\text{m})^2 (\text{m}^2 \cdot \text{kg} \cdot \text{s}^{-3} \cdot \text{A}^{-1} \cdot \text{s}^{-1})}{\text{m}} = \text{A}$$

as expected.

Section 29.4 Electromagnetic Waves

- 13. INTERPRET** We are given the electric and magnetic fields of an electromagnetic wave and asked to find the direction of propagation in terms of a unit vector.

DEVELOP The direction of propagation of the electromagnetic wave is the same as the direction of the cross product $\vec{E} \times \vec{B}$.

EVALUATE When \vec{E} is parallel to \hat{j} and \vec{B} is parallel to \hat{i} , the direction of propagation is parallel to $\vec{E} \times \vec{B}$, or $\hat{j} \times \hat{i} = -\hat{k}$.

ASSESS For electromagnetic waves in vacuum, the directions of the electric and magnetic fields, and of wave propagation, form a right-handed coordinate system.

- 14. INTERPRET** We are given the description of the electric field of a radio wave and are asked to characterize it by finding the peak electric field and the direction of propagation.

DEVELOP The maximum of the sine function is unity, so the prefactor of the sine function gives the peak electric field. In vacuum, the magnetic field must be perpendicular to the electric field. The latter is oriented at 45° above the x-axis for $\sin(kz - \omega t) > 0$, so we can find possible directions for the magnetic field.

EVALUATE (a) When the sine function is unity, the electric field is $E(\hat{i} + \hat{j})$, so its peak magnitude is $E\sqrt{2}$ and its direction is 45° above the x -axis.

(b) To be perpendicular to the electric field, the magnetic field may either be in the $+135^\circ$ from the x -axis (i.e., second quadrant), or -45° from the x -axis (i.e., fourth quadrant). These fields would have unit vectors of $(-\hat{i} + \hat{j})/\sqrt{2}$ and $(\hat{i} - \hat{j})/\sqrt{2}$, respectively.

ASSESS Without knowing the direction of propagation of the electromagnetic wave, we cannot determine absolutely the direction of the magnetic field. The direction of propagation of the electric field is in the direction of $\vec{E} \times \vec{B}$, and so would be in either the \hat{k} or $-\hat{k}$ direction, respectively.

Section 29.5 Properties of Electromagnetic Waves

- 15. INTERPRET** This problem involves expressing the distance between the Sun and the Earth in terms of light minutes.

DEVELOP A light minute (abbreviated as c-min) is approximately equal to

$$1 \text{ c-min} = (3.0 \times 10^8 \text{ m/s})(60 \text{ s}) = 1.8 \times 10^{10} \text{ m}$$

On the other hand, the mean distance of the Earth from the Sun (an astronomical unit) is about $R_{SE} = 1.5 \times 10^{11} \text{ m}$.

EVALUATE In units of c-min, R_{SE} can be rewritten as

$$R_{SE} = (1.5 \times 10^{11} \text{ m}) \frac{\overbrace{1 \text{ c-min}}^{\approx 1}}{1.8 \times 10^{10} \text{ m}} = 8.3 \text{ c-min}$$

ASSESS The result implies that it takes about 8.3 minutes for the sunlight to reach the Earth.

- 16. INTERPRET** This problem is to give you a “feel” for the speed of light. You are to find the approximate time it would take for an electromagnetic signal to travel to a satellite and back.

DEVELOP Assuming the satellite is approximately overhead, we can estimate the round-trip travel time by $\Delta t = \Delta r/c$, where $c = 3.00 \times 10^8 \text{ m/s}$ is the speed of light in vacuum.

EVALUATE The approximate round-trip time is $(2 \times 36,000 \text{ km}) / (3 \times 10^5 \text{ km/s}) = 0.24 \text{ s}$.

ASSESS This explains the very slight delay one may notice in intercontinental phone calls.

- 17. INTERPRET** In this problem we want to deduce the airplane’s altitude by measuring the travel time of a radio wave signal it sends out. The logic of this method is the same as that of the preceding problem.

DEVELOP The speed of light is $c = 3 \times 10^8 \text{ m/s}$ and the total distance traveled is $\Delta r = 2h$ (neglecting the distance traveled by the plane during the transit time of the signal).

EVALUATE Since $\Delta r = 2h = c\Delta t$ (for waves traveling with speed c), the altitude h is

$$h = \frac{c\Delta t}{2} = \frac{(3.00 \times 10^8 \text{ m/s})(74.7 \times 10^{-6} \text{ s})}{2} = 11.2 \text{ km}$$

ASSESS The airplane is flying at about the typical cruising altitude of 12,000 m (35,000 ft) for commercial jet airplanes.

- 18. INTERPRET** This is another problem designed to give a “feel” for the speed of light. We are to find the time it takes for an electromagnetic wave to travel 1 foot (in vacuum).

DEVELOP The speed of light in vacuum is $c = 3.00 \times 10^8 \text{ m/s}$, so the time may be found by dividing the distance (1 foot $\sim 0.30 \text{ m}$) by this speed.

EVALUATE The time t for light to travel 1 foot in vacuum is approximately

$$t = \frac{d}{c} = \frac{0.30 \text{ m}}{3.00 \times 10^8 \text{ m/s}} = 1 \text{ ns}$$

ASSESS This time delay may be measured by modern electronics. Faster times, however, are better measured using optical methods.

- 19. INTERPRET** This problem involves finding the round-trip time delay for radio signals traveling between the Earth and the Moon.

DEVELOP The time it takes to get a reply is twice the distance (out and back) divided by the speed of light, which is 3.00×10^8 m/s in vacuum.

EVALUATE From Appendix E, we find the distance between the Earth and the Moon to be $R_{\text{ME}} = 3.85 \times 10^8$ m, so the time required is

$$\Delta t = \frac{2R_{\text{ME}}}{c} = \frac{2(3.85 \times 10^8 \text{ m})}{3.00 \times 10^8 \text{ m/s}} = 2.57 \text{ s}$$

ASSESS The signal has to travel a very long distance, so a time delay of 2.57 seconds is not surprising. The time delay via geostationary satellite communication is typically between 240 ms and 280 ms (see Problem 29.18).

- 20. INTERPRET** This problem involves converting frequency of light to wavelength.

DEVELOP Equation 29.16c gives λ and wavelength: $f\lambda = c$.

EVALUATE (a) For an FM radio wave,

$$\lambda = \frac{c}{f} = \frac{3.0 \times 10^8 \text{ m/s}}{108 \text{ MHz}} = 2.8 \text{ m}$$

(b) For a WiFi signal,

$$\lambda = \frac{c}{f} = \frac{3.0 \times 10^8 \text{ m/s}}{2.4 \text{ GHz}} = 12.5 \text{ cm} \approx 13 \text{ cm}$$

(c) For a visible light wave,

$$\lambda = \frac{c}{f} = \frac{3.0 \times 10^8 \text{ m/s}}{620 \text{ THz}} = 484 \text{ nm} \approx 480 \text{ nm}$$

(d) For an X-ray,

$$\lambda = \frac{c}{f} = \frac{3.0 \times 10^8 \text{ m/s}}{2.0 \text{ EHz}} = 1.5 \text{ Å}$$

ASSESS From 2.8 m to 1.5 Å, the electromagnetic spectrum that we are most familiar with extends across more than 10 orders of magnitude.

- 21. INTERPRET** In this problem, we are asked to find the wavelength of electromagnetic radiation that propagates through air, given its frequency.

DEVELOP The wavelength of the electromagnetic wave can be calculated using Equation 29.16c: $f\lambda = c$. Because air is not optically dense, it may be taken to be a vacuum, so the speed of light is $c = 3.00 \times 10^8$ m/s.

EVALUATE The wavelength in a vacuum (or air) is

$$\lambda = \frac{c}{f} = \frac{3.00 \times 10^8 \text{ m/s}}{50 \text{ Hz}} = 6.00 \times 10^6 \text{ m}$$

ASSESS The wavelength is almost as large as the radius of Earth!

- 22. INTERPRET** The distance between wave crests is the wavelength of the wave, which we are to find for an electromagnetic wave in vacuum given its frequency.

DEVELOP Apply Equation 29.16c, $\lambda = c/f$, with $c = 3.00 \times 10^8$ m/s and $f = 2.45 \times 10^9 \text{ s}^{-1}$.

EVALUATE The distance between wave crests is

$$\lambda = c/f = (3.00 \times 10^8 \text{ m/s}) / (2.45 \times 10^9 \text{ Hz}) = 0.122 \text{ m} = 12.2 \text{ cm}$$

ASSESS The result is reported to three significant figures.

- 23. INTERPRET** This problem involves finding the direction of polarization of an electromagnetic wave, which is the direction in which the electric field oscillates.

DEVELOP The direction of propagation of the electromagnetic wave is the same as the direction of the cross product $\vec{E} \times \vec{B}$. In our case, we have $\vec{E} \times \vec{B} = \hat{k}$, where \hat{k} is the unit vector in the +z-direction.

EVALUATE Since the magnetic field points in the $+y$ -direction, $\vec{B} = B\hat{j}$, we must have $\vec{E} = E\hat{i}$, so that $\hat{i} \times \hat{j} = \hat{k}$. The wave is linearly polarized in the $+x$ -direction.

ASSESS For electromagnetic waves in vacuum, the directions of the electric and magnetic fields, and of wave propagation, form a right-handed coordinate system. One may write $\vec{E} \times \vec{B} = \hat{n}$, where \hat{n} is the unit vector in the direction of propagation.

- 24. INTERPRET** We are to find the angle between the polarization of the electromagnetic wave (i.e., the direction of its electric field) and the polarization direction of the polarizing material.

DEVELOP Apply the Law of Malus, Equation 29.18.

EVALUATE From the Law of Malus, $S/S_0 = \cos^2 \theta = 20\%$, or $\theta = \cos^{-1}(\sqrt{0.20}) = 63^\circ$.

ASSESS By rotating the polarizer with respect to the incident electromagnetic field, the transmission can be adjusted from almost 100% to almost 0%.

- 25. INTERPRET** This problem is about the intensity of a light beam that transits a polarizer. We are given the angle between the polarization of the light (i.e., its electric field) and the polarization direction of the material.

DEVELOP The intensity of the light after emerging from a polarizer is given by the Law of Malus (Equation 29.18), $S = S_0 \cos^2 \theta$, where θ is the angle between the field and the polarization direction of the material.

EVALUATE The Law of Malus gives $S/S_0 = \cos^2(69^\circ) = 13\%$.

ASSESS The intensity depends on $\cos^2 \theta$. The limit $\theta = 0$ corresponds to the situation in which the direction of polarization of the incident light is the same as the preferred direction specified by the polarizer, and $S = S_0$. On the other hand, when $\theta = 90^\circ$, essentially no light passes through the polarizer.

Section 29.8 Energy and Momentum in Electromagnetic Waves

- 26. INTERPRET** We are to find the intensity of an electromagnetic wave given the strength of its maximum electric field.

DEVELOP Apply Equation 29.20b, $\bar{S} = E_p^2 / (2\mu_0 c)$.

EVALUATE The intensity is

$$\bar{S} = \frac{(1500 \text{ V/m})^2}{2(4\pi \times 10^{-7} \text{ H/m})(3.00 \times 10^8 \text{ m/s})} = 2.98 \times 10^3 \text{ W/m}^2 \approx 3.0 \text{ kW/m}^2$$

ASSESS This is comparable to the average solar intensity at the surface of the Earth, which is about 1370 W/m^2 .

- 27. INTERPRET** This problem explores the average intensity of a laser beam required for dielectric breakdown in air.

DEVELOP The average intensity of an electromagnetic wave is given by Equation 29.20:

$$\bar{S} = \frac{E_p B_p}{2\mu_0} = \frac{c B_p^2}{2\mu_0} = \frac{E_p^2}{2\mu_0 c}$$

EVALUATE With $E_p = 3 \times 10^6 \text{ V/m}$, the average intensity is

$$\bar{S} = \frac{E_p^2}{2\mu_0 c} = \frac{(3 \times 10^6 \text{ V/m})^2}{2(4\pi \times 10^{-7} \text{ N/A}^2)(3.00 \times 10^8 \text{ m/s})} = 1 \times 10^{10} \text{ W/m}^2$$

ASSESS We need a very powerful laser to produce the breakdown field strength. The laser intensity can be compared to the average solar intensity which is about 1370 W/m^2 .

- 28. INTERPRET** We're asked to calculate the electric field inside a microwave oven of a given power.

DEVELOP If we assume the microwaves travel through the oven as plane waves, then the average intensity is related to the power by $\bar{S} = P/A$, where A is the cross-sectional area of the oven. The average intensity is proportional to the square of the peak electric field in the light (Equation 29.20b): $\bar{S} = E_p^2 / 2\mu_0 c$.

EVALUATE Equating the two intensity equations from above, we can solve for the peak electric field:

$$E_p = \sqrt{\frac{2\mu_0 c P}{A}} = \sqrt{\frac{2(4\pi \times 10^{-7} \frac{\text{N}}{\text{A}^2})(3.0 \times 10^8 \text{ m/s})(1.1 \text{ kW})}{(750 \text{ cm}^2)}} = 3.3 \text{ kN/C}$$

ASSESS The answer can also be written as 3.3 kV/m. This is almost four times the peak electric field of sunlight hitting the Earth's surface (recall Example 29.3).

- 29. INTERPRET** You want to know if your new radio can pick up a signal from a remote location.

DEVELOP Given the minimum electric field that the radio can pick up, the minimum intensity is $\bar{S} = E_p^2 / 2\mu_0 c$ (Equation 29.20b).

EVALUATE The radio's intensity threshold is

$$\bar{S} = \frac{E_p^2}{2\mu_0 c} = \frac{(450 \text{ } \mu\text{V/m})^2}{2(4\pi \times 10^{-7} \frac{\text{N}}{\text{A}^2})(3.0 \times 10^8 \text{ m/s})} = 0.27 \text{ nW/m}^2$$

This means you will be able to hear your favorite station at your remote cabin.

ASSESS The minimum detectable signal for a radio or other receiver is usually set by the background noise. A radio station's signal has to be significantly more powerful than stray electromagnetic waves that contribute to the "static" we hear between stations.

- 30. INTERPRET** This problem involves finding the average intensity and the peak electric and magnetic field for the given laser pointer.

DEVELOP The average intensity is the power per unit area, so we need only divide the given power by the given area. To find the electric and magnetic fields, apply Equations 29.20b and 29.17, respectively.

EVALUATE (a) The average intensity is

$$\bar{S} = \frac{0.10 \text{ mW}}{\frac{1}{4}\pi (0.90 \text{ mm})^2} = 160 \text{ W/m}^2$$

(b) Equation 29.20b gives

$$E_p = \sqrt{2\mu_0 c \bar{S}} = \sqrt{2(4\pi \times 10^{-7} \text{ N/A}^2)(3.00 \times 10^8 \text{ m/s})(160 \text{ W/m}^2)} = 350 \text{ V/m, and}$$

(c) Equation 29.17 gives

$$B_p = E_p / c = (350 \text{ V/m}) / (3.00 \times 10^8 \text{ m/s}) = 1.2 \text{ } \mu\text{T}.$$

ASSESS This average intensity is much less than that of the Sun's radiation at the surface of the Earth.

- 31. INTERPRET** You want to double the range of your radio station's antenna.

DEVELOP Listeners at a distance of $r = 15 \text{ km}$ from the antenna can pick up your radio station because the intensity, S , inside this perimeter is above a typical radio receiver's threshold. You want to increase the power so that the intensity at $r' = 30 \text{ km}$ is above the threshold. The relation between intensity and power is given in Equation 29.21: $S = P / 4\pi r^2$.

EVALUATE The required power for doubling the range is

$$P' = P \left(\frac{r'}{r} \right)^2 = (4.6 \text{ kW})(2)^2 = 18.4 \text{ kW} \approx 18 \text{ kW}$$

ASSESS We have assumed that the signal from the antenna radiates out uniformly in all directions, but that is not always the case. Some antennas focus their intensity in particular directions. However, no matter what the radiation pattern from the antenna, the power will have to be quadrupled to double the range in a given direction.

EXAMPLE VARIATIONS

- 32. INTERPRET** Given the wavelength, polarization of electric field, and propagation direction of green laser light, we want to determine the wave frequency, as well as the orientation and magnitude of the wave's magnetic field.

DEVELOP We can use the relationship between frequency and wavelength (Equation 29.16c) $c = f\lambda$, to find the frequency of the light, and the relationship between electric and magnetic field (Equation 29.17) $E = cB$, to find the magnetic field amplitude.

EVALUATE (a) The frequency of the green light is equal to

$$f = c/\lambda = (3.00 \times 10^8 \text{ m/s}) / (532 \text{ nm}) = 5.64 \times 10^{14} \text{ Hz}$$

(b) The magnitude of the magnetic field is equal to

$$B = E/c = (2.19 \text{ kV/m}) / (3.00 \times 10^8 \text{ m/s}) = 7.30 \mu\text{T}$$

(c) Finally, we note that since the propagation direction is along the y -axis, and the electric field is polarized along the z -axis, the magnetic field is perpendicular to both, and is thus oriented along the x -axis.

ASSESS Electric and magnetic fields from electromagnetic waves oscillate perpendicular to each other and the propagation direction.

- 33. INTERPRET** Given the frequency, polarization of magnetic field, and propagation direction of infrared radiation, we want to determine the wavelength, as well as the orientation and magnitude of the wave's electric field.

DEVELOP We can use the relationship between frequency and wavelength (Equation 29.16c) $c = f\lambda$, to find the wavelength of the light, and the relationship between electric and magnetic field (Equation 29.17) $E = cB$, to find the electric field amplitude.

EVALUATE (a) The wavelength of the infrared light is equal to

$$\lambda = c/f = (3.00 \times 10^8 \text{ m/s}) / (194 \text{ THz}) = 1.55 \mu\text{m}$$

(b) The magnitude of the electric field is equal to

$$E = cB = (3.00 \times 10^8 \text{ m/s})(328 \mu\text{T}) = 98.4 \text{ kV/m}$$

(c) Finally, we note that since the propagation direction is along the x -axis, and the magnetic field is polarized along the y -axis, the electric field is perpendicular to both, and is thus oriented along the z -axis.

ASSESS Electric and magnetic fields from electromagnetic waves oscillate perpendicular to each other and the propagation direction.

- 34. INTERPRET** Given the wavelength, polarization of electric field, and propagation direction of a radio signal, we want to determine the wave frequency, as well as the orientation and magnitude of the wave's magnetic field.

DEVELOP We can use the relationship between frequency and wavelength (Equation 29.16c) $c = f\lambda$, to find the frequency of the signal, and the relationship between electric and magnetic field (Equation 29.17) $E = cB$, to find the magnetic field amplitude.

EVALUATE (a) The frequency of the signal is equal to

$$f = c/\lambda = (3.00 \times 10^8 \text{ m/s}) / (484 \text{ m}) = 620 \text{ kHz}$$

(b) The magnitude of the magnetic field is equal to

$$B = E/c = (347 \text{ mV/m}) / (3.00 \times 10^8 \text{ m/s}) = 1.16 \text{ nT}$$

(c) Finally, we note that since the propagation direction is due east (in the x - y plane), and the electric field is polarized vertically (along the z -axis), the magnetic field is perpendicular to both, and is thus oscillating along the north-south direction (x - y plane).

ASSESS Electric and magnetic fields from electromagnetic waves oscillate perpendicular to each other and the propagation direction.

- 35. INTERPRET** Given the frequency, polarization of magnetic field, and propagation direction of a radio signal, we want to determine the wavelength, as well as the orientation and magnitude of the wave's electric field.

DEVELOP We can use the relationship between frequency and wavelength (Equation 29.16c) $c = f\lambda$, to find the wavelength of the signal, and the relationship between electric and magnetic field (Equation 29.17) $E = cB$, to find the electric field amplitude.

EVALUATE (a) The wavelength of the signal is equal to

$$\lambda = c/f = (3.00 \times 10^8 \text{ m/s}) / (88.7 \text{ MHz}) = 3.38 \text{ m}$$

(b) The magnitude of the electric field is equal to

$$E = cB = (3.00 \times 10^8 \text{ m/s})(28.5 \text{ nT}) = 8.55 \text{ V/m}$$

(c) Finally, we note that since the propagation direction is due south (in the x - y plane), and the magnetic field is polarized horizontally (in the x - y plane as well), the electric field is perpendicular to both, and is thus oscillating along the vertical direction (along the z -axis).

ASSESS Electric and magnetic fields from electromagnetic waves oscillate perpendicular to each other and the propagation direction.

- 36. INTERPRET** Given the raised transmitted power of a cellphone in a rural area, we are to find how far it can be from the cell tower in the original example.

DEVELOP Equation 29.21, $\bar{S} = \bar{P}/4\pi r^2$, gives the average intensity at a distance r from the phone. Using this expression for \bar{S} in Equation 29.20b gives $\bar{P}/4\pi r^2 = E_p^2/2\mu_0 c$. We will solve for the distance r which would result in the minimum electric field the cell tower can handle.

EVALUATE Solving for r gives

$$r = \sqrt{\frac{\mu_0 c P}{2\pi E_p^2}} = \sqrt{\frac{(1.26 \times 10^{-6} \text{ N/A}^2)(3.00 \times 10^8 \text{ m/s})(3.0 \text{ W})}{2\pi (1.2 \text{ mV/m})^2}} = 11 \text{ km}$$

ASSESS This power increase more than doubles the distance to the cell tower.

- 37. INTERPRET** Given the distance from cell tower to cellphone, we want to determine the transmitter power needed to maintain a reliable connection with the cell tower in the original example.

DEVELOP Equation 29.21, $\bar{S} = \bar{P}/4\pi r^2$, gives the average intensity at a distance r from the phone. Using this expression for \bar{S} in Equation 29.20b gives $\bar{P}/4\pi r^2 = E_p^2/2\mu_0 c$. We will solve for the power P which would result in the minimum electric field the cell tower can handle.

EVALUATE Solving for P gives

$$P = \frac{2\pi r^2 E_p^2}{\mu_0 c} = \frac{2\pi (8.7 \text{ km})^2 (1.2 \text{ mV/m})^2}{(1.26 \times 10^{-6} \text{ N/A}^2)(3.00 \times 10^8 \text{ m/s})} = 1.8 \text{ W}$$

ASSESS The power necessary to reach the tower scales with the square of the distance r .

- 38. INTERPRET** Given the raised transmitted power of *Voyager 1*, and the signal strength which is measured on Earth, we want to determine its distance from Earth.

DEVELOP Equation 29.21, $\bar{S} = \bar{P}/4\pi r^2$, gives the average intensity at a distance r from the phone. Using this expression for \bar{S} in Equation 29.20b gives $\bar{P}/4\pi r^2 = E_p^2/2\mu_0 c$. We will solve for the distance r which would result in the detected signal strength.

EVALUATE Solving for r gives

$$r = \sqrt{\frac{\mu_0 c P}{2\pi E_p^2}} = \sqrt{\frac{(1.26 \times 10^{-6} \text{ N/A}^2)(3.00 \times 10^8 \text{ m/s})(22.4 \cdot 5 \times 10^4 \text{ W})}{2\pi (3.9 \text{ pV/m})^2}} = 2.1 \times 10^{12} \text{ km}$$

ASSESS *Voyager 1* is approximately 140 astronomical units away from Earth.

- 39. INTERPRET** Given the raised transmitted power of the *MRO* and considering the maximum distance between Earth and Mars from which it could transmit data, we want to determine the minimum value for the electric-field amplitude which needs to be detected at the receiving end.

DEVELOP Equation 29.21, $\bar{S} = \bar{P}/4\pi r^2$, gives the average intensity at a distance r from the phone. Using this expression for \bar{S} in Equation 29.20b gives $\bar{P}/4\pi r^2 = E_p^2/2\mu_0 c$. We will solve for the minimum electric-field which would reach the receivers.

EVALUATE Solving for E_p gives

$$E_p = \sqrt{\frac{\mu_0 c P}{2\pi r^2}} = \sqrt{\frac{(1.26 \times 10^{-6} \text{ N/A}^2)(3.00 \times 10^8 \text{ m/s})(100 \cdot 5 \times 10^4 \text{ W})}{2\pi (400 \times 10^6 \text{ km})^2}} = 43 \text{ nV/m}$$

ASSESS To ensure no loss of communication, the sensitivity of these detection devices likely allows detection of even weaker electric field amplitudes.

PROBLEMS

- 40. INTERPRET** This problem involves applying Gauss's law to find the magnetic field induced by a changing electric field in a circular parallel-plate capacitor. The symmetry involved is cylindrical symmetry, so the magnetic field will be constant at a given distance from the axis of the circular capacitor plates and in the plane of the plates.
- DEVELOP** Cylindrical symmetry and Gauss's law for magnetism require that the \vec{B} -field lines be circles around the symmetry axis. For a radius r less than the radius R of the plates, the displacement current is

$$I_d = \epsilon_0 \frac{d\Phi_E}{dt} = \epsilon_0 \left(\frac{d}{dt} \right) \int \vec{E} \cdot d\vec{A} = \epsilon_0 \pi r^2 \frac{dE}{dt}$$

where the integral is over a disk of radius r centered between the plates. Maxwell's form of Ampère's law gives

$$\int \vec{B} \cdot d\vec{L} = 2\pi r B = \mu_0 I_d,$$

where the line integral is around the circumference of the disk. Thus,

$$B = \frac{1}{2} \mu_0 \epsilon_0 r \frac{dE}{dt} = r \left(\frac{dE}{dt} \right) \left(\frac{1}{2c^2} \right)$$

where c is the speed of light (Equation 29.16a).

EVALUATE (a) On the symmetry axis, $r = 0$, so $B = 0$.

(b) For $r = 15 \text{ cm} < R$,

$$B = \frac{1}{2} \frac{(0.15 \text{ m})(1.0 \times 10^6 \text{ V/m} \cdot \text{s})}{(3.00 \times 10^8 \text{ m/s})^2} = 8.3 \times 10^{-13} \text{ T}$$

(c) For $r > R$, the displacement current is

$$I_d = \epsilon_0 \pi R^2 \frac{dE}{dt}, \text{ so } B = \frac{dE}{dt} \left(\frac{R^2}{2c^2 r} \right)$$

At $r = 150 \text{ cm}$,

$$B = \frac{[1.0 \times 10^6 \text{ V/(m} \cdot \text{s)}](50 \text{ cm})^2}{2 (3.00 \times 10^8 \text{ m/s})^2 (150 \text{ cm})} = 9.3 \times 10^{-13} \text{ T}$$

ASSESS The magnetic field strength increases from $r = 0$ to $r = R$, then decreases beyond $r = R$.

- 41. INTERPRET** This problem involves the rate of change of the electric field, which induces a magnetic field. Given the magnetic field strength at 50 cm from the center, we are to find the rate of change of the electric field and whether it is increasing or decreasing.

DEVELOP The electric and magnetic fields are related by Equation 29.1. If we evaluate the integrals around the circular field line of radius r shown in Fig. 29.15 and the plane area it bounds, we obtain:

$$\int \vec{B} \cdot d\vec{r} = 2\pi r B = \mu_0 \epsilon_0 \frac{d}{dt} \int \vec{E} \cdot d\vec{A} = \frac{1}{c^2} \pi r^2 \frac{dE}{dt}$$

where we have used $c = (\epsilon_0 \mu_0)^{-1/2}$.

EVALUATE (a) Thus, the rate of change of the electric field is

$$\frac{dE}{dt} = \frac{2c^2 B}{r} = \frac{2(3 \times 10^8 \text{ m/s})^2 (1.9 \mu\text{T})}{0.8 \text{ m}} = 4.3 \times 10^{11} \text{ V/(m} \cdot \text{s)}$$

(b) A circulation of \vec{B} clockwise around the circle gives a positive displacement current into the page, so \vec{E} is increasing in this direction.

ASSESS Any change in electric flux results in a displacement current that produces a magnetic field. The displacement current encircled by the loop of radius $r = 0.5 \text{ m}$ is

$$I_d = \epsilon_0 \pi r^2 \frac{dE}{dt} = 3 \text{ A}$$

This is precisely the current a long wire must carry in order to produce the same magnetic field strength at a distance $r = 0.5$ m from its center.

- 42. INTERPRET** The problem simply asks what frequencies correspond to the UVB wavelength range.

DEVELOP The frequency is inversely proportional to the wavelength: $f = c / \lambda$.

EVALUATE The limits of the UVB band in frequency are

$$f_{\min} = \frac{c}{\lambda_{\max}} = \frac{3.0 \times 10^8 \text{ m/s}}{320 \text{ nm}} = 0.94 \times 10^{15} \text{ Hz} = 0.94 \text{ PHz}$$

$$f_{\max} = \frac{c}{\lambda_{\min}} = \frac{3.0 \times 10^8 \text{ m/s}}{290 \text{ nm}} = 1.0 \times 10^{15} \text{ Hz} = 1.0 \text{ PHz}$$

ASSESS Since most people are more familiar with nanometers than with petahertz, the wavelength limits for UV radiation are more often given than the frequency limits.

- 43. INTERPRET** We are to find the magnetic field strength of an electromagnetic wave that produces dielectric breakdown in air.

DEVELOP Treating electromagnetic waves in air approximately like those in vacuum, we can apply Equation 29.17, $B = E/c$ to find the magnetic field strength associated with an electric field strength of 3 MV/m.

EVALUATE The magnetic field strength is approximately

$$B = E/c = \frac{3 \times 10^6 \text{ V/m}}{3.00 \times 10^8 \text{ m/s}} = 10 \text{ mT}$$

ASSESS This is some three orders of magnitude larger than the strength of the magnetic field at the surface of the Earth, which ranges from 30 to 60 μT .

- 44. INTERPRET** We are to find the angle between a polarizer's axis and the polarization direction of an electromagnetic wave given that the polarizer blocks 75% of the wave.

DEVELOP Apply the Law of Malus (Equation 29.18).

EVALUATE Equation 29.18 gives $\theta = \cos^{-1} \sqrt{S/S_0} = \cos^{-1} \sqrt{1 - 75\%} = \cos^{-1} \sqrt{\frac{1}{4}} = 60^\circ$.

ASSESS The angle must be between 0 and $\pi/2$.

- 45. INTERPRET** This problem involves finding the fraction of light transmitted through a polarizer as the direction of the incident polarization changes.

DEVELOP The fraction of light transmitted can be found by using the Law of Malus (Equation 29.18),

$S = S_0 \cos^2 \theta$, where θ is the angle between the polarization direction (i.e., the direction of the electric field) in the electromagnetic wave and the polarization direction of the polarizer. Note that, with zero voltage applied, the laser beam polarization is perpendicular to the polarizer, so zero light is transmitted. During the brownout, the electro-optic modulator manages to rotate the polarization by 78° , which is 12° short of the 90° rotation needed for 100% of the laser light to pass through the polarizer. In the Law of Malus, the angle θ measures the angular departure from parallel alignment (i.e., when there is 100% transmission), so we must use $\theta = 12^\circ$ in our calculation.

EVALUATE From Equation 29.18, we find that $S / S_0 = \cos^2(12^\circ) = 96\%$ is transmitted.

ASSESS The intensity of the laser beam depends on $\cos^2 \theta$. The limit $\theta = 0$ corresponds to the situation in which the direction of polarization of the laser beam is the same as the preferred direction specified by the polarizer, and $S = S_0$.

- 46. INTERPRET** We are to find the intensity of an initially unpolarized light beam after it passes through two linear polarizers oriented at the given angle.

DEVELOP Only 50% (one half the intensity) of the unpolarized light is transmitted through the first polarizer, and the second cuts this down by $\cos^2 35^\circ$ (Law of Malus, Equation 29.18).

EVALUATE Therefore $\frac{1}{2} \cos^2(35^\circ) = 34\%$ of the unpolarized intensity gets through both polarizers.

ASSESS Most of the intensity is lost transiting the first polarizer.

- 47. INTERPRET** We are to find the intensity of a light beam after passing through two polarizers that are oriented at different angles to the polarization direction of the light. Note that the second polarizer is oriented perpendicular to the initial polarization, so we may expect that no light is transmitted.

DEVELOP The intensity of the light after emerging from the first polarizer is given by the Law of Malus (Equation 29.18), $S = S_0 \cos^2 \theta_1$, where θ_1 is the angle between the electric field and the first polarizer's axis. After passing through the first polarizer, the electric field is rotated to the angle θ_1 and so makes an angle $\theta_2 - \theta_1$ with the axis of the second polarizer. Thus, the intensity of the light transmitted through both polarizers is

$$S/S_0 = \cos^2 \theta_1 \cos^2 (\theta_2 - \theta_1)$$

EVALUATE Two successive applications of Equation 29.18 yield

$$\frac{S}{S_0} = \cos^2 (60^\circ) \cos^2 (90^\circ - 60^\circ) = \left(\frac{1}{2}\right) \left(\frac{3}{4}\right) = 0.1875 \approx 19\%$$

ASSESS To see that the result makes sense, let's solve the problem in two steps. The intensity of the beam after passing the first polarizer with $\theta_1 = 60^\circ$ is $S_1 = S_0 \cos^2 \theta_1$. Since the angle between the first and the second polarizers is $\theta_2 = 90^\circ - 60^\circ = 30^\circ$, so upon emerging from the second polarizer, the intensity becomes

$$S_2 = S_1 \cos^2 \theta_2 = (S_0 \cos^2 \theta_1) \cos^2 \theta_2$$

which is the same as above.

- 48. INTERPRET** This problem is about the rate of change of electric field, which induces a magnetic field. Given the magnetic field strength from integration around the page border, we are to find the rate of change of the electric field and whether it is increasing or decreasing.

DEVELOP The electric and magnetic fields are related by Equation 29.1. We are dealing with a rectangular page, for which we measure the area to be: $A = 8.5 \text{ in} \times 10.875 \text{ in} = 0.060 \text{ m}^2$. We are told the result of the magnetic field integral around the page, so we can solve for the rate of change in the electric field as:

$$\begin{aligned} \int \vec{B} \cdot d\vec{l} &= \mu_0 \epsilon_0 \frac{d}{dt} \int \vec{E} \cdot d\vec{A} = \frac{1}{c^2} A \frac{dE}{dt} \\ \frac{dE}{dt} &= \frac{c^2}{A} \int \vec{B} \cdot d\vec{l} \end{aligned}$$

where we have used $c = (\epsilon_0 \mu_0)^{-1/2}$

EVALUATE (a) Thus, the rate of change of electric field is

$$\frac{dE}{dt} = \frac{(3.00 \times 10^8 \text{ m/s})}{(0.06 \text{ m}^2)} (5.12 \times 10^{-8} \text{ T} \cdot \text{m}) = 7.70 \times 10^{10} \text{ V/m} \cdot \text{s}$$

(b) The result of the \vec{B} field integral is positive by going clockwise around the page, meaning a positive displacement current is found going into the page. Since \vec{E} points out of the page, it must be decreasing in this direction.

ASSESS Any change in electric flux results in a displacement current that produces a magnetic field, whose direction will depend on whether the flux is increasing or decreasing.

- 49. INTERPRET** We want to determine how much of a microwave oven's radiation can leak out its door and still be below regulation standards.

DEVELOP If we assume power is leaking uniformly out the door, then the maximum power allowed is just the intensity limit multiplied by the area: $P_{\text{max}} = S_{\text{lim}} A$.

EVALUATE The fraction of power that is allowed to leak out the oven door is

$$\frac{P_{\text{max}}}{P} = \frac{S_{\text{lim}} A}{P} = \frac{(5.0 \text{ mW/m}^2)(40 \text{ cm} \times 17 \text{ cm})}{900 \text{ W}} = 3.8 \times 10^{-7} \approx 0.00004\%$$

ASSESS This is less than one part in a million. It might be surprising, therefore, that a metal screen with holes in it could provide this good of protection. The holes in the metal are much smaller than the microwave wavelength ($\sim 12 \text{ cm}$), which means very little of the radiation can pass through.

- 50. INTERPRET** From the astronomical data in Appendix E and the given intensity of the Sun's radiation at the surface of the Earth, we are to estimate the Sun's total power output.

DEVELOP If the Sun emits isotropically, its power output is $P = 4\pi r^2 \bar{S}$ (from Equation 29.21). A sphere with a radius of one Earth orbit has a surface of $4\pi R_{SE}^2$, so the total power is the power P_E in 1 square meter multiplied by the total surface area of this sphere.

EVALUATE The power output of the Sun is approximately

$$P = 4\pi R_{SE}^2 P_E = 4\pi (1.496 \times 10^{11} \text{ m})^2 (1360 \text{ W/m}^2) = 3.82 \times 10^{26} \text{ W}$$

ASSESS This is a significant power output. Note that the condition that the Sun radiates isotropically becomes better for greater distances from the Sun (or from any source, for that matter). The official value found in the inside back cover of the textbook lists this as $3.828 \times 10^{26} \text{ W}$, where the discrepancy is due to Earth's orbit not being perfectly circular.

- 51. INTERPRET** The problem asks for a comparison of power output between a star and a quasar. The two objects have the same brightness but are at different distances from Earth.

DEVELOP The average intensity of radiation received determines the apparent brightness, so $\bar{S}_{\text{quasar}} = \bar{S}_{\text{star}}$. Apply Equation 29.21 to find the relative power from each source.

EVALUATE From Equation 29.21, $S = P / (4\pi r^2)$, we see that the above condition implies that

$$\left(\frac{P}{r^2} \right)_{\text{quasar}} = \left(\frac{P}{r^2} \right)_{\text{star}}$$

if both behave like isotropic sources (which should be a good approximation; see Problem 29.46). Thus,

$$\frac{P_{\text{quasar}}}{P_{\text{star}}} = \left(\frac{1 \times 10^{10} \text{ y}}{5.7 \times 10^4 \text{ y}} \right) = 3.1 \times 10^{10}$$

ASSESS The luminosity of a quasar is comparable to that of a galaxy of stars!

- 52. INTERPRET** We're asked to characterize the electromagnetic properties of a typical laser pointer.

DEVELOP Assuming the laser's power is distributed uniformly over the beam cross-section, then the intensity is just the power divided by the area: $S = P / \pi r^2$. If the beam points directly into a person's eye, the total energy delivered before the eye blinks will be $U = P\Delta t$. Finally, the peak electric field can be found with Equation 29.20b: $E_p = \sqrt{2\mu_0 c S}$.

EVALUATE (a) The laser beam intensity is

$$S = \frac{P}{\pi r^2} = \frac{1 \text{ mW}}{\pi (0.9 \text{ mm})^2} = 393 \text{ W/m}^2 \approx 390 \text{ W/m}^2$$

(b) The energy delivered before blinking is

$$U = P\Delta t = (1 \text{ mW})(250 \text{ ms}) = 0.25 \text{ mJ}$$

(c) The peak electric field in the laser is

$$E_p = \sqrt{2\mu_0 c S} = \sqrt{2 \left(4\pi \times 10^{-7} \frac{\text{T} \cdot \text{m}}{\text{A}} \right) (3.0 \times 10^8 \text{ m/s}) (393 \text{ W/m}^2)} = 0.54 \text{ kV/m}$$

ASSESS Notice that the laser pointer's intensity is comparable to the intensity of noontime sunlight on a clear day (see Example 29.3). Both light sources could damage your eyes if you forced yourself to look at them long enough.

- 53. INTERPRET** We are to find the transmitted power and the peak electric field in the given electromagnetic wave.

DEVELOP Equations 29.21 and 29.20b can be combined to express the average power output of an isotropic transmitter in terms of the peak electric field at a distance r :

$$P = 4\pi r^2 \left(\frac{E_p^2}{2\mu_0 c} \right)$$

EVALUATE (a) The transmitted power is

$$P = 4\pi r^2 \left(\frac{E_p^2}{2\mu_0 c} \right) = \frac{4\pi (2.0 \text{ km})^2 (350 \text{ mV/m})^2}{2(4\pi \times 10^{-7} \text{ T} \cdot \text{m/A})(3 \times 10^8 \text{ m/s})} = 8.2 \text{ kW}$$

(b) Since $r^2 E_p^2$ is a constant,

$$E'_p = (r/r') E_p = \frac{2.0 \text{ km}}{10 \text{ km}} (350 \text{ mV/m}) = 70 \text{ mV/m}$$

at a distance of 10 km.

ASSESS This signal is still strong enough to be captured by modern radios. Checking the units for part (a), we find

$$\frac{(\text{km})^2 (\text{V/m})^2}{(\text{N/A}^2)(\text{m/s})} = \frac{(\text{m})^2 (\text{m} \cdot \text{kg} \cdot \text{s}^{-3} \cdot \text{A}^{-1})^2 (\text{A})^2}{(\text{kg} \cdot \text{m/s}^2)(\text{m/s})} = \text{m}^2 \cdot \text{kg} \cdot \text{s}^{-3} = \overbrace{(\text{m}) \underbrace{(\text{kg} \cdot \text{m/s}^2)}_{\text{N}} \underbrace{(\text{s}^{-1})}_{\text{J}}}_{\text{W}} = \text{W}$$

54. INTERPRET This problem involves finding the peak electric and magnetic field strengths of electromagnetic radiation, given the average power of the light source and the distance to the light source.

DEVELOP For an isotropic source of electromagnetic waves (in a medium with vacuum permittivity and permeability), Equations 20.20 and 20.21 give

$$\bar{S} = \frac{P}{4\pi r^2} = \frac{E_p B_p}{2\mu_0} = \frac{c B_p^2}{2\mu_0} = \frac{E_p^2}{2\mu_0 c}$$

EVALUATE The peak electric field strength is

$$E_p = \sqrt{\frac{2\mu_0 c P}{4\pi r^2}} = \sqrt{\frac{2(4\pi \times 10^{-7} \text{ T} \cdot \text{m/A})(3 \times 10^8 \text{ m/s})(60 \text{ W})}{4\pi (1.7 \text{ m})^2}} = 35.3 \text{ V/m} \approx 35 \text{ V/m}$$

Using Equation 29.17, we find the peak magnetic field strength to be $B_p = E_p / c = 117 \text{ nT}$, to two significant figures.

ASSESS The field strengths due to the light bulb are rather small.

55. INTERPRET This problem is about the rate of change of electric field, which induces a magnetic field. Given the rate of change of electric field present in a region, we want to determine the magnitude of the induced magnetic field at two different distances from the center of the region.

DEVELOP The electric and magnetic fields are related by Equation 29.1. We are dealing with a circular region of radius R , for which we know the magnitude and sign of the rate of change of electric field present. Since we are interested in the magnetic field induced at two distances: $r_a = 0.5R$, and $r_b = 1.5R$, we can write the field in these two regions as

$$\begin{aligned} \int \vec{B} \cdot d\vec{l} &= \mu_0 \epsilon_0 \frac{d}{dt} \int \vec{E} \cdot d\vec{A} \\ B_a \cdot 2\pi r_a &= \frac{1}{c^2} \pi r_a^2 \frac{dE}{dt} \\ B_b \cdot 2\pi r_b &= \frac{1}{c^2} \pi R^2 \frac{dE}{dt} \end{aligned}$$

where we have used $c = (\epsilon_0 \mu_0)^{-1/2}$

EVALUATE (a) The magnitude of the magnetic field halfway to the edge of the region is equal to

$$B_a = \frac{r_a}{2c^2} \frac{dE}{dt} = \frac{(50.0 \text{ cm})}{2(3.00 \times 10^8 \text{ m/s})^2} (4.88 \times 10^{10} \text{ V/m} \cdot \text{s}) = 136 \text{ nT}$$

(b) The magnitude of the magnetic field outside the region is equal to

$$B_b = \frac{R^2}{2r_b c^2} \frac{dE}{dt} = \frac{(1\text{m})^2}{2(1.50\text{m})(3.00 \times 10^8 \text{ m/s})^2} (4.88 \times 10^{10} \text{ V/m} \cdot \text{s}) = 181 \text{ nT}$$

ASSESS The largest magnetic field will be found right at the edge of the region, where all the electric field flux is enclosed.

- 56. INTERPRET** This problem asks for the energy and momentum carried by the light from a camera flash.

DEVELOP The energy U is the average power times the duration of the flash, and the momentum is simply given by $p = U/c$ (see section on momentum and radiation pressure).

EVALUATE (a) The total energy the flash carries is $U = Pt = (4.5 \text{ kW})(1.0 \text{ ms}) = 4.5 \text{ J}$.

(b) The momentum is

$$p = \frac{U}{c} = \frac{4.5 \text{ J}}{3 \times 10^8 \text{ m/s}} = 1.5 \times 10^{-8} \text{ kg} \cdot \text{m/s}$$

ASSESS A camera flash works by storing energy in a capacitor and then rapidly releasing the energy to cause a quick, bright flash of light.

- 57. INTERPRET** We are to find the average intensity and the peak electric field of the light from a laser, given its average power and its beam diameter.

DEVELOP Intensity is defined as power per unit area. We know that the power of the beam is $P = 6.0 \text{ W}$ and the area is $A = \pi r^2$, where $r = d/2 = 5.0 \times 10^{-4} \text{ m}$, so we can find the intensity. Intensity is also given by the Poynting vector, $S = EB/\mu_0 = E^2/\mu_0 c$, from which we can determine the peak electric field.

EVALUATE (a) $S = P/A = (6.0 \text{ W}) / [\pi (5.0 \times 10^{-4} \text{ m})^2] = 7.6 \times 10^6 \text{ W/m}^2$.

(b) $E = \sqrt{S\mu_0 c} = \sqrt{(7.6 \times 10^6 \text{ W/m}^2)(4\pi \times 10^{-7} \text{ T} \cdot \text{m/A})(3.0 \times 10^8 \text{ m/s})} = 54 \text{ kV/m}$.

ASSESS This intensity is one of the factors that makes a laser beam so dangerous. Seven watts is really not much power, but when packed into such a small area, it gives an enormous intensity.

- 58. INTERPRET** Given the intensity of the laser beam, we are asked to find the corresponding radiation pressure it exerts on a light-absorbing surface.

DEVELOP The radiation pressure generated by a totally absorbed electromagnetic wave of given average intensity can be calculated using Equation 29.22: $P_{\text{rad}} = \bar{S}/c$.

EVALUATE Inserting the values given, the radiation pressure is

$$P_{\text{rad}} = \frac{\bar{S}}{c} = \frac{180 \text{ W/cm}^2}{3.00 \times 10^8 \text{ m/s}} = 6.0 \text{ mPa}$$

ASSESS The pressure is a lot smaller compared to the normal atmospheric pressure of $P_{\text{atm}} = 1.013 \times 10^5 \text{ Pa}$.

- 59. INTERPRET** We will use Newton's third law (Chapter 4) and the radiation momentum generated by the given flashlight to find the time it takes the astronaut to accelerate from rest to 10 m/s .

DEVELOP By Newton's third law, the reaction force of the light emitted on the flashlight equals the rate at which momentum is carried away by the beam, or $F = dp/dt = (dU/dt)/c = P/c$. Such a force could accelerate a mass m from rest to a speed v in time $t = v/a = mv/F = mcv/P$.

EVALUATE For the values given for the astronaut and flashlight,

$$t = \frac{(79 \text{ kg})(3.00 \times 10^8 \text{ m/s})(10 \text{ m/s})}{1.0 \text{ W}} = 2.4 \times 10^{11} \text{ s} = 7.5 \times 10^3 \text{ y}$$

ASSESS This is impractically long, as one might expect.

- 60. INTERPRET** In this problem we calculate the energy and momentum transfer to the *StarChip* sails discussed in the Application: Starshot.

DEVELOP We are told the laser power used to accelerate the starships, so we can determine the energy transfer during a given increment of time. From this energy we can then determine the momentum transferred, and the final speed of the spacecraft.

EVALUATE (a) From the 34 GW of laser power that are reflected from the sails over the 10-minute burst, the energy transfer is equal to

$$\Delta U = P\Delta t = (34 \text{ GW})(10 \times 60 \text{ s}) = 20 \text{ TJ}$$

(b) The momentum associated with this energy transfer is equal to

$$p = \frac{\Delta U}{c} = \frac{(20 \text{ TJ})}{(3.00 \times 10^8 \text{ m/s})} = 6.8 \times 10^4 \text{ kg} \cdot \text{m/s}$$

(c) The final speed of the sails can be determined by looking at this as an elastic collision between the incoming photons and the stationary starship

$$p_{pi} = -p_{pf} + p_{sf} \rightarrow p_{sf} = p_{pi} + p_{pf} = 2p$$

where we have taken the magnitudes of the initial and final photon momenta as equal since the 34 GW used to calculate the energy transfer is the portion that is reflected from the sail. We then find the final velocity is

$$v_s = 2 \frac{p}{m_s} = \left(2 \frac{\Delta U}{c^2 m_s} \right) c = \left(2 \frac{(34 \text{ GW})}{(3.00 \times 10^8 \text{ m/s})^2 (2.4 \text{ g})} \right) = 0.18 c$$

ASSESS The sails are more effective at transferring the photon momentum into translational kinetic energy since they are reflective rather than absorptive. The later would result in half the final velocity we found here.

- 61. INTERPRET** This problem involves finding the radiation pressure at the surface of a white dwarf, given its power and radius.

DEVELOP From Problem 29.46, the Sun radiates $P = 3.85 \times 10^{26} \text{ W}$, and the radius of the Earth is $6.37 \times 10^6 \text{ m}$. Equation 29.22 gives the radiation pressure on a perfect absorber as $p_{\text{rad}} = \bar{S}/c$ and the intensity may be found using Equation 29.21, $\bar{S} = P/(4\pi r^2)$.

EVALUATE Combining the expressions above gives a radiation pressure of

$$p_{\text{rad}} = \frac{P}{4\pi r^2 c} = \frac{3.85 \times 10^{26} \text{ W}}{4\pi (6.37 \times 10^6 \text{ m})^2 (3.00 \times 10^8 \text{ m/s})} = 2.52 \text{ kPa}$$

ASSESS This is some 100 times less than the atmospheric pressure at the surface of the Earth.

- 62. INTERPRET** In this problem, we explore the electric and magnetic fields in a cylindrical resistor and are to show that the Poynting vector averaged over the surface area is $I^2 R$.

DEVELOP Consider the sketch below of the cylindrical resistor, where the hashed portion is the cross section of the cylinder. Assume that the current is steady, and that the fields are independent of time. Ohm's law gives

$$E = J/\sigma = I/(\sigma A)$$

in the direction of the current (see Section 24.3). The magnetic field at the surface, $B = \mu_0 I/(2\pi r)$, encircles the current in the direction of a right-hand screw. Thus \vec{E} is perpendicular to \vec{B} , and

$$\vec{S} = \vec{E} \times \vec{B}/\mu_0$$

points radially into the resistor, as per the right-hand rule. Power flows from the fields into the resistor only through the curved portion of its cylindrical surface, so we can find the power by integrating the Poynting vector component parallel to the surface normal over the surface of the resistor.

EVALUATE The power flowing into the resistor is

$$P = \int \vec{S} \cdot d\vec{A} = \left(\frac{1}{\mu_0} EB \right) (2\pi r L) = \frac{1}{\mu_0} \left(\frac{I}{\sigma A} \right) \left(\frac{\mu_0 I}{2\pi r} \right) 2\pi r L = I^2 \left(\frac{L}{\sigma A} \right) = I^2 R$$

ASSESS This is a special case of Poynting's theorem applied to steady fields.

- 63. INTERPRET** From the transmission percentage of a stack of polarizers, we are to determine how many polarizers the stack contains. We shall use the Law of Malus.

DEVELOP The Law of Malus (Equation 29.18) is $S = S_0 \cos^2 \theta$, where θ is the angle between the polarization of the impinging light beam and the polarization direction of the polarizer sheet. For this problem, $\theta = 14^\circ$. The first polarizer eliminates 50% of the initially unpolarized light, and each subsequent polarizer is equivalent to multiplying the amount of light remaining by $\cos^2 \theta$, so the total percentage of the light that comes through the stack of n polarizers is $S = S_0 \frac{1}{2} (\cos^2 \theta)^{n-1}$. We are given that $S = 0.37 S_0$, so we can solve for n .

EVALUATE The number n of polarizer sheets is

$$\begin{aligned} 0.37 S_0 &= S_0 \frac{1}{2} (\cos^2 \theta)^{n-1} \\ \ln(0.74) &= (n-1) \ln(\cos^2 \theta) \\ n &= \frac{\ln(0.74) + \ln(\cos^2 \theta)}{\ln(\cos^2 \theta)} = 6 \end{aligned}$$

ASSESS The stack has six sheets. If you got 17.5 sheets, you probably forgot that the first sheet eliminates *half* the unpolarized incident light.

- 64. INTERPRET** You want to evaluate an hypothesis that the Sun's radiation pressure cleared out small particles from the early solar system.

DEVELOP The pressure applied by radiation is the intensity divided by the speed of light: $p_{\text{rad}} = S / c$ (Equation 29.22). The Sun radiates uniformly in all directions (with $P = 3.85 \times 10^{26} \text{ W}$, from inside cover), so the radiation pressure decreases as one over the distance squared: $p_{\text{rad}} = P / 4\pi cr^2$. A small particle with radius R will have one face ($A = \pi R^2$) exposed to this pressure. We assume that the particle absorbs the radiation, but does not reflect it, so it will absorb the momentum and thus experience a radiation force of

$$F_{\text{rad}} = p_{\text{rad}} \pi R^2 = \frac{P}{4cr^2} R^2$$

In comparison, the gravitational force on the same particle will be

$$F_g = \frac{GM_s m}{r^2} = \frac{4\pi GM_s \rho}{3r^2} R^3$$

where we have used the density to write the mass as a function of the particle's radius.

EVALUATE The radiation force will point outward, away from the Sun, while the gravitational force will point inward. You want to know at what particle radius will the two forces cancel each other:

$$\begin{aligned}
 R &= \frac{3P}{16\pi GM_s \rho c} \\
 &= \frac{3(3.85 \times 10^{26} \text{ W})}{16\pi \left(6.67 \times 10^{-11} \frac{\text{N} \cdot \text{m}^2}{\text{kg}^2} \right) (1.99 \times 10^{30} \text{ kg}) (2 \text{ g/cm}^3) (3.0 \times 10^8 \text{ m/s})} = 0.29 \text{ } \mu\text{m}
 \end{aligned}$$

ASSESS Particles smaller than this radius would presumably have been blown out of the early solar system. Larger particles would have stuck around to form planets, comets, and other solar system bodies. The particle size discrimination does not depend on the distance from the Sun because both the radiation force and gravitational force are proportional to $1/r^2$.

65. INTERPRET We will use Maxwell's equations to derive the wave equation for electromagnetic radiation.

DEVELOP We will start with the differential form of Faraday's law: $\partial E / \partial x = -\partial B / \partial t$ (Equation 29.12) and differentiate it with respect to x . Then we will take the differential form of Ampère's law: $\partial B / \partial x = -\epsilon_0 \mu_0 \partial E / \partial t$ (Equation 29.13) and differentiate it with respect to t . The combination of these two equations should match that of the generic wave equation (Equation 14.5):

$$\frac{\partial^2 y}{\partial x^2} = \frac{1}{v^2} \frac{\partial^2 y}{\partial t^2}$$

EVALUATE Taking the derivatives specified above, we have

$$\frac{\partial^2 E}{\partial x^2} = -\frac{\partial^2 B}{\partial x \partial t} \quad \frac{\partial^2 B}{\partial t \partial x} = -\epsilon_0 \mu_0 \frac{\partial^2 E}{\partial t^2}$$

Since the order of the partial derivatives is irrelevant, the magnetic field derivatives in the two equations are equal, so we get

$$\frac{\partial^2 E}{\partial x^2} = \epsilon_0 \mu_0 \frac{\partial^2 E}{\partial t^2}$$

This has the same form as Equation 14.5, which implies the electric field behaves as a wave with speed $c = 1 / \sqrt{\epsilon_0 \mu_0}$. By reversing the differentiations, we can show the exact same thing for the magnetic field.

ASSESS As described in Chapter 14, the solution to the wave equation is any function of the form $f(x \pm vt)$. So electromagnetic waves do not necessarily have to be sine waves, but any shape of wave can be analyzed as the sum of individual sine waves (see Fig. 14.18).

66. INTERPRET We are to find the speed of an electromagnetic wave in a medium of dielectric constant κ .

DEVELOP If we replace all instances of ϵ_0 with $\kappa \epsilon_0$, then our result will be the same as before but with $\epsilon_0 \rightarrow \kappa \epsilon_0$.

EVALUATE The speed of light in a vacuum is $c = 1 / \sqrt{\epsilon_0 \mu_0}$. We make the substitution $\epsilon_0 \rightarrow \kappa \epsilon_0$ and obtain

$$v = \frac{1}{\sqrt{\kappa \epsilon_0 \mu_0}} = \frac{1}{\sqrt{\kappa}} \frac{1}{\sqrt{\epsilon_0 \mu_0}} = \frac{c}{\sqrt{\kappa}}$$

ASSESS We could obtain the same result with more effort by going through the whole derivation again, making the replacement $\epsilon_0 \rightarrow \kappa \epsilon_0$ at each step.

67. INTERPRET We are to find the half wavelength of the given electromagnetic radiation.

DEVELOP We use the relationship between frequency and wavelength (Equation 29.16c) $c = f\lambda$, to find the wavelength of the signal, then divide by 2.

EVALUATE The length of the antennas should be

$$L = \frac{1}{2} \lambda = c / (2f) = (3.00 \times 10^8 \text{ m/s}) / (2 \times 2.4 \text{ GHz}) = 6.25 \text{ cm}$$

$$L = \frac{1}{2} \lambda = c / (2f) = (3.00 \times 10^8 \text{ m/s}) / (2 \times 5.0 \text{ GHz}) = 3.00 \text{ cm}.$$

ASSESS The antennas commonly used for Wi-Fi routers are called half-wave dipole antennas and utilize a pair of conductors each $\frac{1}{4}$ of the wavelength long.

68. INTERPRET You want to show that solar power could potentially meet our energy needs.

DEVELOP The total sunlight reaching the Earth's surface will depend on clouds and other atmospheric effects, but for simplicity you can assume that all of the Sun's intensity within the cross-sectional area of the Earth reaches the ground. That means the total power that could potentially be tapped is $P = \bar{S} \cdot \pi R_E^2$.

EVALUATE The average solar intensity at Earth's distance from the sun is

$$\bar{S}_E = \frac{P_S}{4\pi r^2} = \frac{3.85 \times 10^{26} \text{ W}}{4\pi (1.50 \times 10^{11} \text{ m})^2} = 1.36 \text{ kW/m}^2$$

This quantity is called the "solar constant." Multiplying by the cross-sectional area of Earth, the total incident solar power is

$$P = \bar{S}_E \cdot \pi R_E^2 = (1.36 \text{ kW/m}^2) \pi (6.37 \times 10^6 \text{ m})^2 = 1.73 \times 10^5 \text{ TW}$$

This is nearly 10,000 times the current global power consumption of human beings. So there seems to be sufficient potential in solar power.

ASSESS If you take the total power and divide by the surface area of the Earth, you get a very rough estimate of the average solar intensity at a point on the Earth (i.e., accounting for day-night and seasonal effects):

$$\bar{S}_{\text{surf}} = \frac{P}{4\pi R_E^2} = \frac{1}{4} \bar{S}_E = \frac{1}{4} (1.36 \text{ kW/m}^2) = 340 \text{ W/m}^2$$

Let's assume that current solar power collectors are about 10% efficient at converting solar radiation into electricity, in which case the amount of area you'd need to cover with solar collectors to meet global demand would be approximately

$$A \approx \frac{P_{\text{demand}}}{e \cdot \bar{S}_{\text{surf}}} = \frac{18 \text{ TW}}{(0.1)(340 \text{ W/m}^2)} = 530,000 \text{ km}^2$$

This is about the size of Spain, although if such a grand project were realized, it would clearly be better to distribute the solar collectors evenly across the planet.

69. INTERPRET We want to calculate the intensity of Earth's emitted infrared radiation at the Sun's distance from Earth, knowing the amount of energy which is absorbed by Earth from the Sun.

DEVELOP We are told the rate at which sunlight reaching the Earth's surface is absorbed is very nearly equal to the rate at which Earth emits infrared radiation. Knowing the Earth's surface area, we can determine the total power emitted, and using the distance from Earth to the Sun found in Appendix E, we can estimate the intensity of that infrared radiation reaching the Sun.

EVALUATE The total power of emitted infrared radiation from Earth is equal to

$$P = S \cdot 4\pi R_E^2 = (239 \text{ W/m}^2) (4\pi) (6.37 \times 10^6 \text{ m})^2 = 1.22 \times 10^5 \text{ TW}$$

Thus, the intensity reaching the Sun is equal to

$$S = \frac{P}{4\pi R_{\text{StoE}}^2} = \frac{(1.22 \times 10^5 \text{ TW})}{(4\pi) (149.6 \times 10^9 \text{ m})^2} = 431 \text{ nW/m}^2$$

ASSESS This is a very small value, showing that although the absorption and emission rates on Earth are nearly the same, the amount of infrared intensity reaching the Sun from Earth is quite negligible. This small difference in absorption and emission rate from Earth reflects a slight imbalance of about 0.5 W/m^2 associated with anthropogenic global warming.

70. INTERPRET From a measurement of electric field at some distance from an antenna, we are to estimate the power radiated from the antenna. We will assume that the antenna radiates uniformly in all directions, and use the inverse-square law (see Equation 29.21).

DEVELOP We are told that the electric field at a distance $R = 4.6 \text{ km}$ is $E = 380 \text{ V/m}$. With the Poynting vector

$$S = \frac{EB}{\mu_0} \text{ and } E = cB$$

we can then find the intensity at this distance. From the area of the sphere at this distance and the intensity, we can calculate the total power coming from the antenna.

EVALUATE The total power coming from the antenna is

$$P = AS = \pi R^2 E^2 / (c\mu_0) = \pi (4.6 \text{ km}) (380 \text{ V/m}) / \left[(3.00 \times 10^8 \text{ m/s}) (4\pi \times 10^{-7} \text{ N/A}^2) \right] = 25.5 \text{ kW}.$$

ASSESS One thing to consider is that the transmission antenna does *not* radiate uniformly in all directions, so the actual power may be somewhat different depending on the relative elevation difference between the measurement location and the antenna, assuming the antenna is vertical. However, this is probably a good estimate, and the actual power of the antenna is likely to be *lower* if the measurement point is at about the same elevation as the antenna. The station is broadcasting legally.

- 71. INTERPRET** We are to find the peak electric and magnetic fields of the light from the lasers in the National Ignition Facility, given its average power and beam cross section.

DEVELOP Intensity is defined as power per unit area. We know that the average power of the beam is

$$\bar{P} = \frac{10.0 \text{ kJ}}{20 \text{ ns}} = 5.0 \times 10^{11} \text{ W}$$

and the cross-sectional area is $A = l^2 = (0.38 \text{ m})^2 = 0.1444 \text{ m}^2$, so we can find the average intensity, which is given by the Poynting vector,

$$\bar{S} = \overline{EB}/\mu_0 = \frac{E_p^2}{2\mu_0 c} = \frac{cB_p^2}{2\mu_0},$$

from which we can determine the peak electric and magnetic fields.

EVALUATE (a) The average intensity is

$$\bar{S} = \frac{\bar{P}}{A} = \frac{5.0 \times 10^{11} \text{ W}}{0.1444 \text{ m}^2} = 3.46 \times 10^{12} \text{ W/m}^2$$

Thus, the peak electric field is

$$E_p = \sqrt{2\bar{S}\mu_0 c} = \sqrt{2(3.46 \times 10^{12} \text{ W/m}^2)(4\pi \times 10^{-7} \text{ N/A}^2)(3.00 \times 10^8 \text{ m/s})} = 5.1 \times 10^7 \text{ V/m}$$

(b) Using $B_p = E_p / c$, we find the peak magnetic field to be

$$B_p = \frac{E_p}{c} = \frac{5.1 \times 10^7 \text{ V/m}}{3.0 \times 10^8 \text{ m/s}} = 0.17 \text{ T}$$

(b) The combined power of the 192 beams is

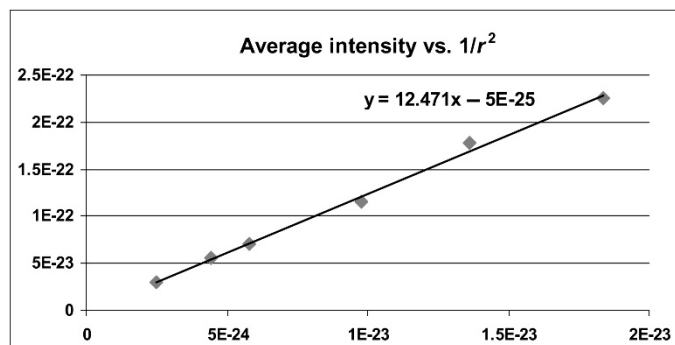

$$\bar{P}_{\text{total}} = 192\bar{P} = 192(5.0 \times 10^{11} \text{ W}) = 9.6 \times 10^{13} \text{ W} = 96 \text{ TW}$$

ASSESS The power is about six times the rate of energy consumption of humankind.

- 72. INTERPRET** We're given the data of the average intensity of radio signals received at Earth from a spacecraft on its way to the outer solar system. By analyzing the data, we are to deduce the transmitting power of the spacecraft.

DEVELOP If we assume that the spacecraft's transmitter broadcasts its radio signal uniformly in all directions, then the intensity at Earth will be $\bar{S} = \bar{P} / 4\pi r^2$, where \bar{P} is the average emitted power and r is the distance from Earth. Thus, $\bar{S} = (\bar{P} / 4\pi)(1/r^2)$, and if we plot \bar{S} versus $1/r^2$, we will obtain a straight line with slope equal to $\bar{P} / 4\pi$, which allows us to deduce \bar{P} .

EVALUATE The plot is shown below.

The slope of the best-fit line is 12.471 W, from which we find the spacecraft's transmitted power to be

$$\bar{P} = 4\pi(12.471 \text{ W}) = 156.7 \text{ W}$$

ASSESS The average intensity falls off as $1/r^2$. In arriving at the result above, we used $1 \text{ AU} = 1.496 \times 10^{11} \text{ m}$ as the conversion factor.

73. INTERPRET We're asked to consider the potential of solar sail technology.

DEVELOP The solar sail is accelerated by the radiation pressure from the Sun: $p_{\text{rad}} = \frac{1}{c}S$ (Equation 29.22). We don't know the area or the mass of the sail, but since the Sun's intensity decreases as one over the distance squared, so will the acceleration: $a \propto 1/r^2$.

EVALUATE The acceleration near Mars will be less than the acceleration near Earth. More specifically,

$$a_M = a_E \left(\frac{r_E}{r_M} \right)^2 = 1 \text{ m/s}^2 \left(\frac{1}{1.5} \right)^2 = 0.4 \text{ m/s}^2$$

The answer is **(b)**.

ASSESS The acceleration of the sail is not large, but it never "shuts off" like a rocket engine does, so the speed can build up over time. Using the fact that $a dr = v dv$, we can integrate the sail's acceleration from Earth's orbital radius to that of Mars:

$$\int_{r_E}^{r_M} a_E \left(\frac{r_E}{r} \right)^2 dr = a_E r_E \left(1 - \frac{r_E}{r_M} \right) = \int v dv = \frac{1}{2} v^2$$

where we have assumed that the solar sail started at rest at Earth. Plugging in the values from above, the sail's speed once it reaches Mars would be about 300 km/s.

74. INTERPRET We're asked to consider the potential of solar sail technology.

DEVELOP The rate at which light waves carry momentum per unit area is $\frac{1}{c}S$, so an object that absorbs this light over an area A and during time Δt will gain in momentum by $\Delta p = \frac{1}{c}SA\Delta t$. However, if the light is reflected rather than absorbed, then the light's momentum is reversed and the object's gain in momentum will be double:

$$\Delta p = 2 \cdot \frac{1}{c}SA\Delta t.$$

EVALUATE Since the acceleration is proportional to the momentum change: $a = \Delta p / m\Delta t$, a reflective sail should have twice the acceleration of the absorptive sail.

The answer is **(b)**.

ASSESS We've assumed here that the reflective sail is flat, and the incoming light is normal to its surface. If the sail happened to be curved or tilted, then the reflected light would not be directed back toward the Sun, and the change in momentum would be less than twice that of the absorptive case.

75. INTERPRET We're asked to consider the potential of solar sail technology.

DEVELOP In the previous problems, we have argued that the radiation pressure and the force it applies to the sail are proportional to $1/r^2$. This is also true of the gravitational force.

EVALUATE Since Jupiter is roughly five times further from the Sun than Earth, the sail force at Jupiter's position will be 25 times smaller. However, the gravitational force from the Sun will also be 25 times smaller, so the sail force will still be 20 times solar gravity.

The answer is **(d)**.

ASSESS For the sail force to dominate gravity, the sail must be lightweight with a large surface area. We can write the ratio of the forces in terms of the area and the mass:

$$\frac{F_{\text{rad}}}{F_g} = \frac{p_{\text{rad}} A}{GM_S m / r^2} = \frac{P_{\text{em}}}{4\pi GM_S c} \left(\frac{A}{m} \right)$$

where we have written the Sun's intensity in terms of the emitted power: $P_{\text{em}} = 3.85 \times 10^{26} \text{ W}$. Plugging this in with the mass of the Sun, $M_S = 1.99 \times 10^{30} \text{ kg}$, we get

$$\frac{m}{A} \approx 0.8 \text{ g/m}^2 \left(\frac{F_g}{F_{\text{rad}}} \right)$$

What this says is that each gram of spacecraft requires more than a square meter of sail if the radiation force is to overcome gravity.

76. INTERPRET We're asked to consider the potential of solar sail technology.

DEVELOP We're given the Sun's intensity and the area of the sail, so the force from radiation is

$$F_{\text{rad}} = p_{\text{rad}} A = \frac{SA}{c} = \frac{(1.4 \text{ kW/m}^2)(1 \text{ km}^2)}{3.0 \times 10^8 \text{ m/s}} = 4.7 \text{ N}$$

EVALUATE For the given mass of 100 kg, the spacecraft should accelerate at about 5 cm/s^2 .

The answer is **(b)**.

ASSESS The mass to area ratio of this sail is $m/A = 0.1 \text{ g/m}^2$. Plugging this into the equation we derived in the previous problem, we see that the gravitational force on the sail will be about 1/8th that of the radiation force.
